Minerals Yearbook
1972

Volume I

METALS, MINERALS, AND FUELS

Prepared by staff of the

BUREAU OF MINES

UNITED STATES DEPARTMENT OF THE INTERIOR ● Rogers C. B. Morton, Secretary

BUREAU OF MINES ● Thomas V. Falkie, Director

As the Nation's principal conservation agency, the Department of the Interior has basic responsibilities to protect and conserve our land and water, energy and minerals, fish and wildlife, and park and recreation areas, and for the wise use of all those resources. The Department also has a major responsibility for American Indian reservation communities and for the people who live in Island Territories under U.S. administration.

Foreword

For 91 years, the Federal Government, through the medium of the Minerals Yearbook or its predecessor volumes, has reported annually on mineral industry activities. This edition of the Minerals Yearbook presents the record on worldwide mineral industry performance during 1972. In addition to statistical data, the volumes provide sufficient background information to interpret the year's developments. The content of the individual volumes is as follows:

Volume I, Metals, Minerals, and Fuels, contains chapters on virtually all metallic, nonmetallic, and mineral fuel commodities important to the domestic economy. In addition, it includes a general review chapter on the mineral industries, a statistical summary, and a chapter on technologic trends.

Volume II, Area Reports: Domestic, contains chapters on the mineral industry of each of the 50 States, the U.S. island possessions in the Pacific Ocean and the Caribbean Sea, the Commonwealth of Puerto Rico, and the Canal Zone. This volume also has a statistical summary, identical to that in Volume I.

Volume III, Area Reports: International, contains the latest available mineral data on more than 130 foreign countries and discusses the importance of minerals to the economies of these nations. A separate chapter reviews minerals in general and their relationships to the world economy.

The Bureau of Mines continually strives to improve the value of the Yearbook for its users, and toward that end, the constructive comments and suggestions of readers will be welcomed.

THOMAS V. FALKIE, *Director.*

Acknowledgments

Volume I, Metals, Minerals, and Fuels, of the Minerals Yearbook summarizes the significant data pertaining to mineral commodities obtained as a result of the mineral intelligence gathering activities of the divisions and offices of the Assistant Directorate—Mineral Supply.

The collection, compilation, and analysis of the data on the domestic minerals and mineral fuel industries were performed by the staffs of the Divisions of Ferrous Metals, Fossil Fuels, Nonferrous Metals, and Nonmetallic Minerals. Statistical data were compiled by the statistical staffs of these Divisions from information supplied by mineral producers, processors, and users in response to production and consumption canvasses, and their voluntary response is gratefully acknowledged. The information obtained from individual firms by means of confidential surveys has been grouped to provide statistical aggregates. Data on individual firms are presented only if available from published or other nonconfidential sources or when permission of the companies has been granted. Other material appearing in this volume was obtained from the trade and technical press, industry contacts, and numerous other sources.

Statistics on U.S. imports and exports, world production, and foreign country trade were compiled in the Office of Technical Data Services. The foreign trade data for the United States were obtained from reports of the Bureau of the Census, U.S. Department of Commerce. World production and trade data came from numerous sources, including reports from the Foreign Service, U.S. Department of State.

The Office of Technical Data Services also provided general direction on the preparation and coordination of the chapters in this volume and reviewed the manuscripts to insure statistical consistency among the tables, figures, and text, between this volume and other volumes, and between this edition and those of former years.

Acknowledgment is also particularly made of the splendid cooperation of the business press, trade associations, scientific journals, international organizations, and other Federal agencies that supplied information.

The Bureau of Mines has been assisted in collecting mine-production data and the supporting information appearing in the Minerals Yearbook by numerous cooperating State agencies. These organizations are listed in the acknowledgment to Volume II.

ALBERT E. SCHRECK, *Editor-In-Chief*

Review of the Mineral Industries

By Daniel E. Sullivan,[1] Jeannette I. Baker,[2] and Nicholas G. Theofilos[3]

The U.S. economy was expansive in 1972. Output, income, and employment all increased substantially. The unemployment rate declined only slightly. Inflation moderated but not for food commodities. Monetary policy was loose at the beginning of the year but tightened somewhat in the closing months. Fiscal policy was also expansive. During 1972, Phase II controls on prices and wages were in effect. This allowed fiscal and monetary policy to be more flexible.

Output as measured by the gross national product (GNP) increased 9.75% in 1972. Real GNP grew at a rate of 6.5%, the largest full-year advance since 1966; and the implicit price deflator rose 3.8%, the smallest full-year advance since 1966. All major sectors except for net exports contributed to the overall increase. Significant increases occurred in gross private domestic investment, Federal purchases in the first half of the year, and consumer spending. The Federal Reserve Board (FRB) Index of Industrial Production increased more than 7%.

Employment in 1972 continued the strong growth trend that characterized the second half of 1971. However, the labor force also increased substantially so unemployment declined only slightly from 5.9% in 1971 to 5.6% in 1972. Unemployment was close to the 1971 level in the first 5 months of the year, but by the fourth quarter it had declined to an average of about 5.3%. The increase in employment was strongest in the durable goods manufacturing industries. The increase in the labor force was greatest for adult women.

The rate of inflation in 1972 was less than that of 1971 for most commodities. Agricultural prices not covered by price controls increased at an accelerated rate during 1972. The overall consumer price index was up 3.3% for the year, compared with 4.3% for 1971. With food prices excluded, the index increased 3.0%. Prices for nonfood commodities were up 2.3% for the year 1972, compared with 3.8% for 1971. Service prices rose 3.8% for 1972, which was less than for recent years. Wholesale prices increased at a greater rate during 1972 than during 1971 wholly because of increases in the prices of agricultural products. The industrial wholesale price index rose about the same during 1972 as for the previous year, 3.4%.

Monetary policy during the year favored economic expansion. Its purpose was to contribute to the goals of economic growth, increased employment, less inflation, and fewer balance of payments problems. The money supply grew at a rate of 8.2% during 1972, the second highest rate since World War II. In 1971 the increase was 6.2%, and in 1970, it was 5.4%. Interest rates were stable in 1972 after declining in late 1971. Mortgage interest rates in 1972 were below those of 1971, and well below those of 1970.

An expansionary Federal fiscal policy resulted from rising expenditures and from the effect of tax reductions instituted in 1971 and 1972. In 1971 there was a small full employment surplus, but in 1972 there was a stimulating full employment deficit.

United States gold reserves declined slightly early in 1972 and then remained constant until May when their value was increased by a change in the price of gold from $32 to $38 per troy ounce. The rest of the year they remained almost unchanged with a slight decline at the end of the year.

Significant Federal activity in 1972 included the continuation of Phase II of the New Economic Policy (NEP). Phase II was designed to be a transition between the freeze of Phase I and less stringent controls. Legislation approved by Congress during 1972 covered many subjects of concern to the minerals industries. These included the environment, water, public land, black-lung disease benefits, consumer safety, the price of gold, and the strategic stockpile.

---

[1] Economist, Office of Economic Analysis—Mineral Supply.

[2] Commodity research specialist, Office of Technical Data Services—Mineral Supply.

[3] Statistical assistant, Office of Economic Analysis—Mineral Supply.

Bureau of Mines research programs continued to be directed toward developing more effective, efficient and less costly extraction, processing, and utilization techniques; improving mine safety; increasing the recovery of secondary resources; and eliminating pollution problems.

The demand for energy continued to be strong, especially for clean-burning fuels. Domestic fuels production expanded at a slower rate than consumption, more fuels were imported, and there were some fuel shortages. Underground mining of coal declined for the third consecutive year primarily because of health and safety regulations. Surface mining increased, and, for the first time in the history of the industry, output from strip mines exceeded that of deep mines. In petroleum, major concerns were import quotas and the construction of the trans-Alaska pipeline. The pipeline would bring Alaskan oil to the contiguous 48 States, but unsettled environmental decisions have delayed its construction.

The metals industry reflected the economy as a whole in 1972. Prices increased as did the demand for metals. There were no major strikes, but concern over environmental problems was widely felt. Output in the nonmetallic mineral industries was high during 1972, despite the fact that environmental problems were significant throughout the industry.

The long-run growth in world trade was maintained in 1972 in spite of turmoil in the international monetary system. The outlook for future modifications in the system appeared good. U.S. balance of payments improved in 1972, although a large deficit still remained.

SOURCES AND USES

ALL MINERALS

Production.—In 1972, domestic production of primary minerals and mineral fuels was valued at $32.2 billion. In 1967 constant dollars, the value of mineral production was $27.0 billion. The value of metals and nonmetals each increased about 7% and mineral fuels advanced 4% over 1971.

The Bureau of Mines total index of physical volume of mineral production (1967=100) increased 2.5% to 112.6 points in 1972. The average for metals increased 4.3% to 127.5 points. Within this group ferrous metals increased 1.5% and nonferrous metals increased 5.7%. In the nonferrous index, base metals increased 7.8%, monetary metals declined 5.4%, and other nonferrous 2.7%. The average for nonmetals increased 5.8%. Construction, chemical, and other nonmetals increased at rates

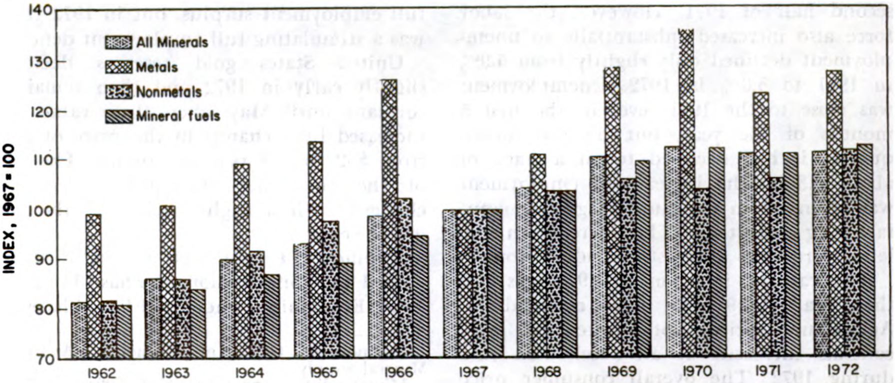

Figure 1.—Indexes of physical volume of mineral production in the United States, by group.

close to the average with the former increasing at a less than average rate and the latter two increasing more than the average. The index for fuels increased 1.2%. The coal index increased 6.2%, and crude oil and natural gas increased from 111.3 to 111.4 points.

The FRB Index of Industrial Production (1967=100) increased more than 7% during 1972, from 106.8 to 114.4 index points. The average for all mining increased from 107.0 to 108.2 index points because of increases in coal mining and stone and earth minerals mining. The former increased over 3%; the latter increased almost 1%. The index for crude oil declined 0.9%, gas and gas liquids declined more than 1%, and metal mining declined only 0.5%.

Industrial production of metals and nonmetals increased significantly in 1972. Primary metals, iron and steel, and nonferrous metals and products increased 12%, 11%, and 14%, respectively, after declining last year. Clay, glass, and stone products, which increased 3% in 1971, increased 7% in 1972.

The FRB monthly indexes of mining production (1967=100) stayed near 108 index points during most of the year except for September, October, and November when it was near 110 index points. The index for coal was mixed during 1972; in July it reached a high of 114.4 points, and in August it came within 0.1 point of the December low of 97.1 points. Crude oil and natural gas increased early in the year and remained fairly level through the rest of the year. Metal, stone, and earth minerals increased for the year after an early decline.

The net supply of principal minerals increased for most commodities during 1972. Ferrous metals followed this trend with pig iron increasing 9.9% to 89,670,000 tons, and steel ingot increasing 9.0% to 147,853,000 long tons. Iron ore, not following the trend, declined 2.3% to 111,545,000 long tons. Of the other ferrous metals, chromite and manganese declined 13% or more while the rest increased. The total net supply of tungsten doubled. Nonferrous metals also followed the trend, with antimony and the platinum-group metals increasing by the greatest margin. The only significant declines in this group were in mercury, rutile, and zinc. Almost all nonmetal group commodities showed increases in net supply, with the exception of sand and gravel, which declined 0.8%. Gypsum and crude barite showed the greatest increases, 23.1% and 16.9%, respectively. The smallest increases were posted by potash, salt, and sulfur.

Stocks and Government Stockpile.—The Bureau of Mines index of stocks of crude minerals (1967=100) for metals and nonmetals declined 4.0% to 142 points in 1972. Metal stocks declined 2.7% to 143 points. Iron ore declined 16.9%. Other ferrous ores increased 156% in 1972, compared with a 196% increase in 1971; both increases were caused by a large increase in molybdenum stocks. Nonferrous metal stocks declined 22.8% to 78 points. Nonmetallic stocks declined 5.4% to 141 points. The index of stocks held by mineral manufacturing consumers and dealers declined 8 points to 95 points in 1972. Metal stocks declined 11 points as all metal subgroups declined at least 8 points with the exception of other ferrous metals stocks, which remained constant. Iron declined 14 points. The index for nonmetals increased 33 points to 121.

Producer stocks of bituminous coal and lignite increased 28% in 1972; coke stocks decreased 17.0%. Stocks of petroleum and related products, with the exception of petroleum asphalt, all declined. Petroleum asphalt increased 2.0%. Crude petroleum decreased 5.1% and gasoline stocks decreased 3.0%. Natural gas stocks remained unchanged in 1972.

The seasonally adjusted book value of product inventories for selected mineral processing industries increased as a whole in 1972 although some industries showed declines. Energy showed a decrease in inventories, and nonmetals and primary metals showed increases in inventories. Petroleum and coal products decreased 9.6% to $2,200 million as of December 1972. Stone, clay, and glass products increased 5.2% to $2,381 million in 1972. The seasonally adjusted book value of primary metals inventories increased 4.6% to $9,619 million. Blast furnace and steel mills inventories, which make up almost 55% of primary metals inventories, increased 9.3%. Other primary metals inventories declined less than 0.5% to $4,375 million. The total seasonally adjusted book value of inventories for selected mineral processing industries increased 2.2% to $14,200 million during the year 1972.

The national stockpile of strategic materials continued to contain an important component of the Nation's mineral supply during 1972. Stockpile commodities of significant market value included aluminum, metallurgical chromite, copper, lead, metallurgical manganese, silver, tin, tungsten, and zinc.

Exports.—The total value of selected minerals and mineral products exported in 1972 was $4,691 million, a 2.3% increase over the comparable 1971 figure. Exports in 1971 had declined more than 21% from those of 1970. The increase was felt in most sectors except for chemicals, which declined 9.3%. Minerals, nonmetallic (crude), exports increased 9.8%. Exports of metals (crude and scrap), mineral energy and related products, and metals (manufactured), all increased at rates close to 4%. Minerals, nonmetallic (manufactured), exports increased 2.6%.

Significant changes in the geographical distribution of selected mineral exports took place in 1972. Last year the Soviet bloc received less than 0.5% of U.S. crude fertilizer exports; in 1972, they received 3%. In 1971 other North American countries received 47% of U.S. exports of petroleum, crude and partially refined; in 1972 they received only 29%, with most of the difference accounted for in exports to Asia. In 1971, 85% of tin and tin alloys was exported to Asia; in 1972 Asia received only 10% of U.S. tin and tin alloys exports. In 1971, 88% of the uranium and thorium and their alloys exports was shipped to North America, but in 1972 only 26% of these exports went to other North American countries and 62% was shipped to Europe.

Imports.—The value of selected mineral imports increased 18.5% to $11,646 million in 1972. All major categories except metals (crude and scrap) increased. Crude nonmetallic minerals increased 7.7% in value to $298 million. Crude and scrap metals declined 2.6% to $991 million. The most important increase was a 30.4% change, to $4,814 million, in the imports of mineral energy resources and related products. Within this group, crude and partly refined petroleum increased 39.3% to $2,593 million. Imports of chemicals increased 25.0% to $541 million. The largest percentage change was a 44.7% increase in the imports of minerals, nonmetallic (manufactured), to $221 million. Imports of metals (manufactured) increased 12.2% to $4,781 million.

The geographical distribution of the source of imports into the U.S. in 1972 changed significantly for certain mineral commodities. In 1971 other North American countries were the source of 66% of copper ores and concentrates imported into the U.S. In 1972 North America was the source of only 14%; Asia, which had supplied none in 1971, supplied 56% of these imports. Other North American countries supplied 34% of the imports into the U.S. of tin waste and scrap in 1971, and Africa supplied 36%; but in 1972 Africa supplied none, and North American countries supplied 71%. In 1971 North American countries supplied 57% of the aluminum waste and scrap imported, and Europe supplied the remainder; but in 1972 North American countries supplied 88% of these imports. Sixty-two percent of imports of tungsten ores and concentrates in 1971 were from North American countries; in 1972 only 30% came from North America, while imports from Asia increased from none to 25% of the total. Imports of mercury, including waste and scrap, decreased from 81% from North American sources in 1971 to 59% in 1972; imports from Africa increased from none to 17%.

Consumption.—Consumption of major mineral products generally increased during 1972. Iron ore consumption increased 9.2% after declining 11.6% in 1971. Raw steel increased 10.6%. All other ferrous metals showed strong increases in consumption. All nonferrous metals increased except uranium, which declined 9.4%. Platinum-group metals consumption increased 23.2%. Antimony and silver both increased 17% or more. Copper and zinc each increased almost 11% and ilmenite and titanium slag increased more than 10%. Lead increased 3.7% but mercury increased only 1.2%.

Consumption of nonmetals increased for all major commodities except sand and gravel, which declined 0.8%. Phosphate rock increased 9.6%, followed by cement, which increased 9.0%. Sulfur increased 7.2%; asbestos, 6.6%; crushed stone, 5.6%; clays, 4.9%; and lime, 3.6%. Salt and potash increased only 0.8% and 0.4%, respectively.

Total energy resource inputs in terms of British thermal units (Btu) increased 5.2% to 72,242 billion Btu. Consumption of all mineral energy resources increased with one exception—anthracite coal declined over 14%. Petroleum consumption increased 7.9%, bituminous coal increased 5.1%, and dry natural gas increased 1.3%.

All categories of electricity generation increased in 1972. The total increased 7.9% to 1,853 billion kilowatt hours. Utilities increased 8.3%, made up by a 3.9% gain in hydropower, a 42.6% gain in nuclear power, and an 8.5% increase in conventional fuel-burning plants. Industrial generation of electricity increased 2.4%.

ENERGY

Demand for energy in 1972 was at the highest level ever. Domestic production did not supply as great a percentage of the U.S. supply as it has in the past. The demand for clean energy has increased faster than the demand for energy as a whole or the ability to produce clean-burning fuels. As a result there was in 1972, as in the previous few years, an "energy crisis." This energy crisis was generally manifested in the form of "brown outs" and shortages of heating fuel in the cold months. As a result, more of the domestic energy needs in 1972 were supplied by imported fuels, and the search for alternative sources of domestic energy was intensified.

Production.—Total production of mineral energy resources and electricity from hydropower and nuclear power in 1972 increased 2.1% to 62,222 trillion Btu. Fossil fuels increased, except for anthracite coal, which declined 18.5% to 181 trillion Btu. Bituminous coal and lignite increased 7.2% to 14,350 trillion Btu. Wet natural gas and crude petroleum both increased less than 0.5% to 24,878 and 19,344 trillion Btu, respectively. Hydropower increased 2.4% to 2,893 trillion Btu, and nuclear power increased 42.6% to 576 trillion Btu.

Consumption.—U.S. energy consumption in 1972 increased 5.2% to 72,242 trillion Btu. Consumption of anthracite coal declined over 14.3%. Bituminous coal and lignite increased 5%, second only to petroleum, which increased over 8% in 1972. Natural gas consumption increased over 1%, and natural gas liquids increased over 2%. Consumption of electricity from hydropower increased almost 4%. Electricity consumption from nuclear power, which was the same as production, increased 42.6%.

Household and commercial received 41.9% of its total energy inputs from natural gas, 36.9% from petroleum, and 19.1% from electric utilities; for industrial users the percentages were 45.9, 24.3, and 10.8, respectively. The transportation sector received 95.5% of its energy from petroleum. Energy inputs to electric utilities were from bituminous coal and lignite, 41.9%; dry natural gas, 22.1%; petroleum, 16.9%; hydropower, 15.8% and nuclear power, 3.1%.

Coal.—The domestic supply of anthracite coal declined 19.4% in 1972; that for bituminous coal and lignite increased 5.0%. Exports of anthracite declined 14.3% and those of bituminous declined 1.2%. Imports of bituminous coal declined 64,000 tons to 47,000 tons in 1972, after increasing 75,000 tons in 1971. The total domestic supply of bituminous coal in 1972 was 519.8 million tons; for anthracite the figure was 5.9 million tons. Electric utilities used 67% of bituminous coal. The household and commercial sector was the largest user of anthracite.

Natural gas.—The domestic supply of natural gas increased 1.3% to 22,429 billion cubic feet in 1972. Domestic production increased 0.2% to 22,532 billion cubic feet. Exports declined 2.7% to 78 billion cubic feet; imports increased 9.1% to 1,019 billion cubic feet. Demand for natural gas increased in all consuming sectors except electric power generation, which declined 0.4%. The largest increase was 3.8% in the household and commercial sector. The largest consuming sector, industrial, consumed 42.9% of the natural gas supply in 1972.

Petroleum.—The domestic supply of petroleum increased 7.9% to 5,990.2 million barrels. Production increased only negligibly to 3,455.4 million barrels; exports declined from 0.5 to 0.2 million barrels; and imports increased 32.2% to 811.1 million barrels. The total supply of crude oil increased 4.7% to 4,280.9 million barrels. Demand for petroleum increased 7.7% to 5,320.7 million barrels. Transportation continued to be the largest consuming sector, accounting for over 60% of petroleum demand.

Geothermal Energy.—The search for new sources of energy has led to the development of geothermal power generation. At the present time it is in use at only a few locations where ideal conditions exist. Other areas considered potential sources of geothermal power were being investigated in 1972.

Nuclear Energy.—Nuclear energy in 1972 contributed less than 1% to total energy consumption in terms of Btu's. Although this is not an impressive number, during 1972 much research was devoted to increasing the energy output from nuclear sources.

Hydroelectric Power.—Hydroelectric power supplied less than 5% of U.S. consumption in 1972. During the year, the increase in the output of hydroelectric plants did not keep up with the rate of increase in the U.S. demand for energy.

Other Energy.—Solar, wind, tidal and biological energies were only minor, or potential sources during 1972. All were being considered as potential sources of energy for the future. Solar and wind energy have been used on only a minor scale. Biological (from organic wastes) and tidal energies were still only in the theoretical stages in 1972.

EMPLOYMENT AND PRODUCTIVITY

Employment.—Employment in selected mineral industries increased for mining, but the manufacturing sector continued to show a decrease for the third consecutive year. Total mining employment increased almost 1% in contrast to last year's decline of 3%. This was mostly accounted for by a 12% increase in copper ore mining and an 8% gain in bituminous coal. Employment in crude petroleum and natural gasfields posted a 2.3% decrease, while oil and gasfield services registered a 3.2% gain. Iron ore mining and nonmetal mining and quarrying employment continued to decline to 20,100 and 112,100, respectively.

In 1972, minerals manufacturing employment decreased almost 2% to 834,800. All categories declined except for cement and petroleum and coal products.

Hours and Earnings.—Hourly earnings for the total mining sector increased 7.8% to $4.17. This increase is slightly better than the trend of recent years. Weekly earnings increased at almost the same rate, since weekly hours declined only 0.1 hour to 43.4. Average hourly earnings for metal mining increased 8.5% to $4.47. Average hourly earnings for iron ore mining increased 7.4% to $4.50, and for copper ore mining they increased 11.1% to $4.62. Average weekly hours for metal mining declined 0.1 hour to 41.5. Average weekly hours for copper ore mining declined 3% to 41.6, and an increase of 1.7% to 41.2 was reported for iron ore mining. Average hourly earnings for nonmetal mining and quarrying increased 7.3% to $3.95; weekly hours remained nearly the same; and weekly earnings increased almost the same percent as hourly earnings. In the mineral fuels industries, average hourly earnings increased 7.3% to $4.53, weekly hours remained constant, and weekly earnings increased 10.2% to $191.27. The highest average hourly and weekly earnings occurred in the bituminous coal mining industry. Weekly hours, weekly earnings, and hourly earnings all increased for crude petroleum and natural gas. Hourly earnings, which declined 2.1% last year, increased 5.9% this year.

Average hourly earnings for manufacturing industries increased 11.8% in 1972. Hourly earnings in the fertilizer industry increased 7.3% to $3.36; weekly earnings increased at a slightly higher rate; and weekly hours increased slightly. In the cement industry hourly earnings increased at about the same rate as last year (10%), to $5.12. Hourly earnings increased 12.7% to $5.15 for the blast furnaces, steel and rolling mills industry; weekly earnings increased 15.8% as weekly hours increased slightly over 1 hour. Hourly earnings in nonferrous smelting and refining increased 10.4%; weekly earnings increased 11.2%; and weekly hours increased only slightly.

Hourly earnings for the petroleum and related products industries increased 8.1% to $4.95. Weekly earnings increased 7.6% as weekly hours declined slightly.

Labor Turnover Rates.—The accession rate (hires and rehires) for selected mineral industries varied in 1972. Two categories remained stable, but three others declined. Of those showing a decline, blast furnaces, steel and rolling mills, and hydraulic cement, decreased by four per thousand employees; and coal mining went from 19 to 18 per thousand employees. Manufacturing, nonferrous smelting and refining, metal mining, iron ores, and copper ores registered moderate increases. The separation rate remained stable in manufacturing, petroleum refining and related industries, and petroleum refining. Separation rates in the metal mining, iron ore, and coal mining industries increased two per thousand over that of 1971. Hydraulic cement, copper ores, and blast furnaces, steel and rolling mills declined, with the latter showing the sharpest decrease. The layoff rate for 1972 was down or stable in most categories with the exception of coal mining, metal mining, and iron ores.

Wages and Salaries.—During 1972 the total wages and salaries for all industries continued to trend upward. The increase was 9.3%, significantly higher than last year's 5.9%. In the mining sector, total wages and salaries reached $6.7 billion. Wages and salaries in manufacturing rose 9.4% to $175.8 billion, a large increase over last year's 1.5% gain. Average yearly earnings per full-time employee for all industries was $8,604, a 6.7% increase. The mining sector employees received an annual average of $10,320 in 1972, a 4% gain over 1971. Average earnings in manufacturing increased 6.9%, to $9,232.

Productivity.—Labor productivity indexes for selected minerals in 1971 (latest data available) showed mixed results. The petroleum refining indexes showed gains in productivity, and the bituminous coal and lignite mining indexes showed losses in productivity. The index of copper ore output per production worker increased in 1971 from 131.9 points in 1970 to 133.5 points (1967=100). The indexes of output per production worker man-hour for copper ore mined and recoverable metal mined increased 5.4% and 1.9%, respectively to 133.8 and 114.9 index points. The index of output per production worker man-hour for iron ore mined increased 2.0% to 119.6 points and the same index for usable ore increased 0.8% to 108.9 points. Productivity of petroleum refined as reflected in the indexes of output per employee, per production worker, and per production worker man-hour all reversed the down-trend of 1970 and increased in 1971; output per production worker man-hour increased 4.3% to 114.9 index points. Productivity of bituminous coal and lignite mining as reflected in these same indexes declined; output per production worker man-hour declined 1.3% to 102.5 index points.

PRICES AND COSTS

Index of Average Unit Mine Value.—The total index of average unit mine value (1967=100) increased 2.3% in 1972, to 120.3. The fuel index increased by 1.7%, metals increased by 3.3% and nonmetals increased by 3.6%. Ferrous metals increased by 3.7%. Nonferrous base metals and other nonferrous metals increased by 0.6% and 0.8%, respectively. Nonferrous monetary metals increased by 26.9% raising the average for all nonferrous metals by 2.9%. The increase in the nonmetals index was caused by a 4.7% increase in construction and a 4.9% increase in other metals; the chemical index declined 1.0%. The coal index increased 6.3%, and crude oil and natural gas increased 0.5%.

Index of Implicit Unit Value.—The index of implicit unit value (1967=100) increased 2.2% to 120.2 in 1972. This is less than one-half the increase of the previous year. The index for ferrous metals increased 3.3%. The average for nonferrous metals increased 2.1%, compared with the 7.9% decline in 1971. Base metals increased slightly, monetary metals increased almost 24% and other nonferrous metals increased 3.3%. Nonmetals increased 3.3% to 110.8. Construction increased 4.4%, chemicals declined 2.4%, and other nonmetals increased 5.2%. The fuels section increased 2.1% from 119.8 to 122.3. The coal index increased 6.4% and that for crude oil and natural gas increased less than 1%.

Prices.—The wholesale price index for all commodities increased 4.6% during 1972. However, the index for all commodities other than farm and food increased only 3.4%. Wholesale prices for metals and metal products increased 3.8%. Within this group, price changes ranged from a 16.6%

decline in aluminum ingot to a 10.7% increase in common pig lead. Prime western slab zinc increased 10.0%. Most other metals prices increased moderately. Prices of most nonmetallics also increased during the year as reflected in the 3.0% increase in the overall nonmetallic index. Gypsum products showed the largest gain in this group with a 7.4% increase. Only three nonmetallic commodity price indexes declined, and two remained unchanged. Fertilizer materials declined 2.0%, phosphates declined 4.7%, and domestic muriate of potash declined 0.1%. Phosphate and total potash remained unchanged. Prices for fuels, related products and power increased 3.9% in 1972. Price indexes for anthracite and bituminous coal increased 4.2% and 6.8%, respectively. Coke increased 4.6%, gas fuel prices increased 5.6%, electric power increased 7.0%, and crude petroleum, and petroleum products increased 0.5% and 2.0%, respectively.

During 1972, mineral energy resource prices were generally up for coal and natural gas and, down for petroleum and petroleum products. Bituminous coal increased more than 15%; anthracite prices increased at rates of almost 3% to more than 5%. Prices of petroleum and petroleum products declined with the exception of crude petroleum which was unchanged at $3.39 per barrel and the price of No. 2 distillate fuel oil for all Gulf ports. Gasoline prices declined over 2%. The average price of natural gas at the wellhead increased over 2% from 18.2 cents to 18.6 cents per thousand cubic feet.

The average cost of electrical energy in the United States in 1971 (latest data available) rose 0.1 cent above that of 1970, to 1.7 cents per kilowatt hour. The average cost of electrical energy in both the residential market and the commercial and industrial markets showed a 0.1-cent increase to 2.2 and 1.4 cents per kilowatt hour, respectively. Costs in all geographic areas with two exceptions either remained unchanged or increased only 0.1 cent per kilowatt hour. The two exceptions were the East South-Central region and the Middle Atlantic region in which the price increased 0.2 and 0.3 cents per kilowatt hour, respectively. Alaska and Hawaii remained the highest cost areas, and the East South-Central region remained the lowest cost area.

Principal Metal Mining Expenses.—The index of principal metal mining expenses (1967=100) continued to climb in 1972, although not so fast as in 1971. Electrical energy reflected the largest increase, 7.0%. The labor component was next, rising 5.9%. Fuels increased 3.9%, compared with 7.8% for the previous year. Of the principal metal mining expenses, the index for supplies again increased at the slowest rate, 3.8%. Overall, the index climbed 5.1%.

Costs.—The 1972 index of relative labor costs and productivity for iron ore showed an increase in productivity; that for copper ore showed a decrease in productivity. The index of labor costs per unit of output for iron ore mining decreased 2.2%; the figure for copper ore mining increased 15.0%. The index of value of product per man-period was up 11.6% for iron ore mining; the figure for copper ore mining declined 5.0%. The index of labor costs per dollar of product for mining iron ore and copper ore declined 3.7% and increased 16.9%, respectively. The index of relative labor costs and productivity for bituminous coal in 1971 (latest data available) showed a 15.1% increase in labor costs per unit of output, an 8.0% increase in the value of product per man-period, and an 8.0% increase in labor costs per dollar of product. The index for petroleum for 1970 (latest data available) showed a 1.5% increase in labor costs per unit of output, an 8.8% increase in the value of product per man-period, and a 0.7% decrease in labor costs per dollar of product.

The range of changes in all but two of the price indexes for mining construction and material handling machinery and equipment during 1972 was between plus 2.8% and plus 4.1%. The exceptions were portable air compressors which decreased 1.9%, and power cranes, drag lines, shovels, etc., which increased 4.5%.

INCOME AND INVESTMENT

National Income Generated.—In 1972 national income originating in all industries was $942 billion, a 9.6% increase over 1971. The mining industries advanced

17.6%, a sharp contrast to last year's 8.6% decline. Crude petroleum and natural gas again increased in 1972, by 27.5%, which was by far the largest increase in any sector. Coal mining increased to $2.4 billion, a 15.7% gain. The mining and quarrying of nonmetallic minerals and metal mining advanced 9.7% and 6.7%, respectively, over 1971. Mineral manufacturing also increased in 1972, to $252 billion, an 11.6% increase. The primary metal industries and the manufacturing of stone, clay, and glass products increased about 13%. Petroleum refining and related industries showed a gain of 9.1%, which was slightly higher than that of 1971.

Profits and Dividends.—In 1972 the average annual profit rate on shareholders' equity in manufacturing industries increased for the second consecutive year. The increase was 9.3%, more than twice the 4.3% increase in 1971. Profit rates for almost all the selected mineral manufacturing corporations posted increases with the exception of the petroleum refining industries. The greatest percentage increase was a 35.6% increase to a rate of 6.1 for primary iron and steel. Primary nonferrous metals increased 15.7% to a rate of 5.9, which was still the lowest annual profit rate among the selected mineral manufacturing corporations. Chemicals and allied products increased 9.3% to a rate of 12.9, which was the highest among the selected corporations. Petroleum refining declined 16.5%, although it paid out the highest level of dividends, $3.3 billion, an increase of 1.8% over that of 1971. The sharpest decline in total dividends was reflected by primary nonferrous metals, a 27.2% decrease from the previous year, followed by primary metals with 13.9%. Stone, clay and glass products reached $415 million in 1972, a 15.9% increase. Primary iron and steel registered a 0.2% increase, a sharp contrast to last year's 21.3% decrease. The total dividends for all manufacturing in 1972 reached $16.1 billion, a 5.8% increase over that of 1971.

The total number of industrial and commercial failures in 1972 declined to 9,566, the lowest figure reported since 1969. This represented a 7.4% decrease, while the current liabilities increased 4.3%, surpassing the $2 billion mark. There were 44 mining failures reported in 1972, compared with 38 in the previous year, but the current liabilities declined by more than $3.5 million. In the manufacturing sector the number of failures declined over 19%, and the current liabilities increased 8.3% over that of 1971.

New Plant and Equipment.—In 1972 new plant and equipment expenditures by mining firms continued to rise, reaching $2.42 billion, a 12% increase over that of 1971. The manufacturing sector, which experienced a decrease last year, came back up to over $31 billion. Among selected mineral manufacturing industries, the expenditures were mixed. The most significant change occurred in stone, clay, and glass products, which increased over 41%. Primary nonferrous metals also increased, from $1.08 billion in 1971 to $1.18 billion in 1972, a 9% gain. Primary iron and steel, and petroleum and coal products registered 10% decreases for 1972.

Plant and equipment expenditures of foreign affiliates of U.S. companies in mining and smelting decreased in 1972 to $1,657 million, a 4% decrease from 1971. The only increase in expenditures was posted by Europe, which gained $2 million over the previous year. Canadian expenditures declined 7%, a sharp contrast to last year's large increase. Latin American expenditures declined 6% to $230 million. The petroleum outlay in 1972 went up again, this year by 10% in comparison with last year's figure of 25%. All reporting areas showed gains in petroleum expenditures except for Latin America. The manufacturing sector rose 13% to 7.6 billion, with Canada the only area to show a decrease.

Issues of Mining Securities.—In 1972, estimated gross proceeds of new securities offered by extractive industries totaled $2,010 million, compared with $1,283 million in 1971. Common stock accounted for 64.7% of the proceeds, substantially less than 1971. The remainder was absorbed by bonds, 35.1%, and preferred stock, 0.2%.

Foreign Investment.—The value of U.S. direct investments abroad for all industries increased 10% to $86.0 billion in 1971 (latest data available). Investments in developed countries, which accounted for 68% of the total, also increased about 10% during the year to $58 billion. Investments in petroleum affiliates accounted for 28%

of the 1971 total. Petroleum investments increased 11.7% in 1971, the rate of increase being about the same in both developed and developing countries. Developed countries accounted for 53% of the investments in petroleum affiliates. In 1971 the book value of Canadian petroleum affiliates gained $327 million. The value of petroleum investments in European affiliates increased $736 million. Investments increased for all developing countries. The other Asia and Pacific section increased almost 36%, the Latin American section increased 6.5%, the other Africa section increased 9.5%, and the Middle East increased only 1.6%.

U.S. direct investments in foreign mining increased $583 million to $6.72 billion during 1971 (latest data available). Net capital outflows increased to $519 million, and reinvested earnings declined. The developed countries accounted for more than 60% of the U.S. direct investments.

The total value of foreign direct investments in the U.S. was $13.7 billion in 1971 (latest data available). Almost 23% of this or $3.1 billion was invested in petroleum. Petroleum gained 4% for the year, much less than the 20% gain the previous year. European firms provided 92% of the petroleum investments; firms in the United Kingdom and the Netherlands alone accounted for 84%.

TRANSPORTATION

The total quantity of selected minerals and mineral energy products transported by railroad and water in the United States declined in 1971 (latest data available), with transportation of mineral products declining at a greater rate than the total for all commodities. Rail transportation of total mineral products declined 8.8%, but water transportation remained steady. Almost 63% of selected metals and minerals, except fuels, was transported by rail, and more than 59% of selected mineral energy resources and related products was transported by water. Total selected minerals and mineral energy products accounted for 57.3% of all commodities transported by rail and 84.3% of all commodities transported by water.

In the metals and minerals except fuels category, the quantity transported by rail decreased 7.3% to 400.9 million short tons. Iron ore and concentrates, crushed and broken stone, sand and gravel, and phosphate rock were the largest users of rail transport in volume terms. Rail transport for most minerals declined in 1971, with the notable exception of slag, which increased 48%; gypsum and plaster rock which increased more than 17%; and phosphate rock, which increased more than 4%. Leading the decline were pig iron, which declined over 23%; other nonferrous ores and concentrates, almost 19%; and iron and steel primary products, over 13%.

In the same category transportation by water decreased in quantity by 0.2% to 239.7 million short tons. Iron ore and concentrates and crushed and broken stone combined with sand and gravel continued to be the largest commodities by volume.

Mineral energy resources transported by rail in 1971 amounted to 396 million short tons, a decline of 10.2% from that of last year. Shipments of bituminous coal and lignite accounted for more than 89% of selected mineral energy resources and related products transported by rail.

Coal and crude petroleum accounted for more than 45% of the tonnage of mineral energy resources transported by water. Large amounts of gasoline and distillate and residual fuel oil were transported by water in 1971. The total volume of selected mineral energy resources and related products transported by water was 558 million short tons, which was very similar to that of 1970.

A total of 935,000 miles of gas pipeline existed in 1971 (latest data available), a 2.2% increase above that of 1970. Total petroleum pipeline mileage in 1971 increased to 219,000 miles. The total petroleum pipeline mileage reported was distributed among the following: crude gathering systems in field operations, 33%; larger size crude trunklines, 34%; and petroleum product pipelines that extend from refineries to extraction terminals, 33%.

RESEARCH ACTIVITIES

National expenditures for research and development activities for all industries in 1971 (latest data available) totaled $18.4 billion, almost a 3% gain over the 1970 expenditure of $17.9 billion. In 1971 company expenditures accounted for $10.7 billion, and the Government funded $7.7 billion; the figures for 1970 were $10.1 billion and $7.8 billion, respectively. Research and development expenditures in petroleum refining and extractive totaled $505 million in 1971, a 16.9% decline from the 1970 figure of $608 million. Almost 97% of the 1971 figure and 93% of the 1970 figure were financed by private expenditures; Government funds supplied the remainder. Research and development expenditures in the chemical and allied products industries were $1.8 billion, very close to the 1970 figure, which was almost 5% greater than the 1969 figure. Company expenditures made up nearly 90% of the total in both 1970 and 1971.

Bureau of Mines.—Bureau research activities continued to be directed toward efficient use of our natural mineral and fuel resources to insure adequate mineral supplies without objectionable environmental, social, and occupational effects. Bureau research programs were divided into the following groups in 1972: mining research, metallurgy research, resource recovery and pollution abatement, coal research, petroleum research, oil shale research, health and safety research, and explosives and explosions research. Economic research was directed toward the same ends as other Bureau of Mines research; it included environmental problems and studies of supply and demand problems.

Bureau of Mines funding of obligations for mining and mineral research and development was $70.9 million during fiscal year 1972, a 17.6% increase above fiscal year 1971. Funds for applied research increased to $32.8 million, 46% of the total. Funds for basic research rose to $7.8 million, 11% of the total, and funds for development increased 40% to $30.2 million, which is 43% of the total. Obligations for fiscal year 1973 are estimated to increase by more than 10% to $78.4 million. Most of this increase is estimated to be funds for development; funds for basic research are estimated to decline. Bureau of Mines funding obligations for total research were $40.6 million in 1972, a 4.7% increase. Funds for engineering sciences were $28.7 million; for physical sciences, $10.5 million; for mathematical sciences, $0.5 million; and for environmental sciences, $0.9 million. The estimated figures for 1973 are very close to the 1972 figures. Highlights of the accomplishments of Bureau research programs, including work in progress, are as follows:

Mining.—Ore recovery ratio is a primary indication of the efficient extraction of our natural resources. As the size of pillars left by mining is decreased, the ore recovery ratio increases. In situ stress measurements and triaxial strength tests on model pillars containing planes of weakness showed conclusively that the in situ strength of full-size mine pillars containing planes of weakness can be predicted with good accuracy. With this information, stable pillars can be designed using safety factors as low as 1.5, a significant improvement over the value of four that is generally used in the design of rock structures. Use of these techniques to predict pillar strength will permit use of the lower safety factor in design and could increase productivity without sacrificing safety.

Other advances in understanding pillar behavior were made as a result of stiff loading tests on model pillars. In the case of a partially failed pillar, it was shown that the decrease of load results mainly from a decrease in the effective cross sectional area of the pillar and that the maximum stress on the undisturbed section remains a constant. This maximum stress can be estimated from the prefailure load-deformation curve. Also confirmed was that the addition of as little as 1 to 4 pounds per square inch radial confining pressure can increase the post-failure strength of pillars by as much as 10%.

Several major improvements were made in in situ stress determination techniques. Accurate stress measurements can now be made in high stress areas where discing occurs by means of a special type of borehole deformation gage that requires only one-half of an inch of overcoring. The necessary corrections have been determined by finite element analysis and proven correct by field tests. An improved type of borehole gage also has been developed which eliminates the drift problem. This gage is sufficiently stable so that it can be used to measure change in stress with time.

A field technique was developed and tested for locating hidden faults that cause serious ground support and hydrologic problems in certain uranium deposits in Wyoming. In another study theoretical analysis has shown that a 2-foot thick layer of sand around an 8-foot diameter corrugated aluminum culvert can reduce the maximum stress by a factor of 10.

Tests on small reinforced polymer-impregnated concrete beams for use as mine supports showed that conventional design concepts might create a condition where reinforced polymer-impregnated beams fail violently. This problem can be solved by the addition of small quantities of steel fibers.

As the first step toward developing a new mining method for the native copper ores of the upper Michigan peninsula, a 5½-month test demonstrated that electronic sorting of coarse ores is feasible. In another research effort on native copper ores, it was found that high-frequency induction heating does not produce the thermal shock necessary for the fragmentation of these ores. However, a combined thermal-hydraulic rock fragmentation technique was successfully tested on other rock types.

Hydraulic pipeline transportation tests to study the effect of particle size on head loss produced surprising results. At high velocities, six sizes of glass heads showed no discernable differences in head loss and all head losses approached clear water behavior as velocity increased. At lower speeds, below 7.5 feet per second, head loss becomes an inverse function of particle size; that is, an increase in particle size resulted in a decrease in head loss, indicating that less energy was dissipated in particle interaction as particle size increased. This is in contradiction to the widely accepted Durand equation, which states that head loss is directly proportional to particle size.

Digging and loading tests on bulk material developed quantitative evidence that approximately four times as much energy is required for the loading process. Thus, any improvement in the initial penetration process could result in considerable saving in both design and operating horsepower.

Metallurgy.—The general objective of the metallurgy program of the Bureau of Mines is to provide, through research and development, the scientific and technical information necessary to encourage and stimulate the nonfuel minerals industry to make advancements in technology. Industry's response and acceptance of Bureau technology was indicated by the construction of a new plant in Mississippi, modeled on the Bureau-developed method for producing electrolytic chromium. It is the only commercial process in use in the United States for producing the metal. The Bureau-developed ion exchange process for recovering uranium values from mine waters, when tested on a semiindustrial scale, was accepted by several commercial uranium producers. In another development, the Bureau's modern version of the carbon-in-pulp gold recovery process was pilot tested in a cooperative effort and then adopted by the Homestake Mining Co. at Lead, S. Dak., where it was shown that gold could be recovered effectively from slimes. As a result of the successful pilot plant investigations, the company has built a new 2,350-ton-per-day carbon-in-pulp plant to replace its old slime plant. Another gold process developed by the Bureau has achieved acceptance for the recovery of gold from domestic deposits at Carlin and Cortez, Nev., where leaching techniques have been successfully applied to submarginal gold ores.

The development of a process to beneficiate nonmagnetic taconites into a commercially acceptable iron ore was also accomplished by Bureau researchers. Although magnetic taconites have been used increasingly as a source of domestic iron ore, large reserves of nonmagnetic taconites have been bypassed for lack of an acceptable beneficiation process. The Bureau conducted a vigorous program on laboratory and pilot plant scale for flotation of nonmagnetic taconites. The results led to a patented method to improve the grade of the ore from 30% iron to over 65% iron in concentrates meeting commercial acceptance. In 1972, after several years of cooperative effort with the Bureau, the Cleveland Cliffs Iron Co. announced plans to allocate $190 million for its Tilden project, which would have an initial annual output of 4 million tons of pellets using the Bureau-developed selective flocculation flotation process on Marquette Range nonmagnetic taconites. This plant will be the first of its kind to process low-grade, fine-grained, nonmagnetic taconite. Research is underway on the development of a new process to recover phosphate while eliminating the slime storage ponds—the major problem in the current extraction technique. Slimes are stored in huge ponds, covering thousands of acres, which precludes the use of this valuable land for other purposes. Another problem is that waste slimes contain more than 20% of the phosphate mined. The Bureau has recently found that direct acidulation of land pebble phosphate ore with sulfuric acid in a continuous miniplant recovered approximately 95% of the phosphate while forming a sandy solid residue which should cause no waste disposal problem. The new process appeared to be technologically feasible, but additional research is necessary to establish the economic and environmental feasibility.

Bureau of Mines research on copper is concerned with extracting the metal from low-grade ore and the development of roast-leach methods for processing concentrates. In one study, a process has been developed to recover copper more effectively from the run-of-mine material deposited in dump piles or heaps. In another study. laboratory research has shown that roasting copper sulfide concentrates (chalcopyrite) with lime followed by acid leaching is effective for obtaining high copper recovery and at the same time eliminating the generation of sulfur dioxide, a serious air pollution problem in conventional roasting and smelting operations. Because the roast is autogenous, considerable gangue can be tolerated in the concentrate. This feature would reduce flotation costs and also save valuable byproduct minerals, such as molybdenite, that are only partially recovered in the present techniques for producing clean concentrate for smelter feed.

In other copper research, a simple and inexpensive sulfatizing roast-leach procedure has been developed for treating copper concentrate from sulfide ores. Roasting the copper concentrate with iron oxide converts essentially all of the contained copper to a water soluble copper sulfate. Gold and silver present in the leach residue are amenable to subsequent recovery. It may be possible for the copper to be recovered by electrowinning or, alternatively, copper can be concentrated readily by solvent extraction. This procedure is environmentally attractive since it concentrates the SO_2, which facilitates the conversion to acid.

The Bureau's materials research effort included studies on ceramics, catalysis, and the rolling and forging of ductile iron. The hot working of ductile iron promises major advantages. First, ductile iron, made primarily from scrap in relatively simple equipment, does not require the degree of refining necessary in steel production. The second advantage is that forgings could be produced from simple shapes cast to near final dimensions. The Bureau's experimental rolling and forging tests have shown that certain ductile iron alloys can be successfully hot worked to obtain final shapes, with properties adequate for many applications where steel is now used. Research is continuing to determine the best conditions under which ductile iron can be worked, including the effects of starting materials and compositions.

Ceramic and nonmetallic minerals research in the Bureau was directed toward increasing the availability of such products as replacements for metals and as a means of improving the efficiency of minerals and metals processing. The Bureau began a new research program on more effective methods to process, fabricate, and utilize nonmetallic minerals and materials. Research under this program included testing clays and a variety of ceramic materials in applications that will expand the use of these resources, developing drilling fluids and modified portland cements for use in high-temperature and high-pressure drill hole applications such as are encountered in very deep oil wells, and creating new uses for low-cost sulfur and waste sulfate products. The work on testing and evaluation of ceramic raw materials was designed to provide technical assistance to State geologists.

Resource Recovery and Pollution Abatement.—The metallurgy research program also included a wide variety of projects on secondary materials recovery and pollution abatement studies on mineral processing wastes, which are described in the Bureau's Information Circular 8595.

Bureau of Mines research has resulted in the development of an effective and technologically feasible process for the desulfurization of stack gases. The relatively straight-forward method, known as the "citrate process," was originally designed to remove sulfur dioxide from the stack gases of smelters treating sulfide ores. The process is now being evaluated for controlling emissions from fossil fuel fired powerplants, chemical processing plants, and oil refining operations.

The Bureau is currently constructing a pilot plant at Kellogg, Idaho, which will treat stack gas from the lead smelter operated by the Bunker Hill Company. The plant will process about 1,000 cubic feet per minute of gas containing 0.5% sulfur dioxide. Sulfur dioxide removal is expected to be over 98%.

An independent pilot plant test of the citrate process also is underway as a joint effort of Pfizer Inc., Arthur G. McKee and Co., and Peabody Engineering.

Control regulations for sulfur dioxide air pollution are expected to create an abundant supply of low-cost sulfur and sulfuric acid. The Bureau has initiated a program to develop new uses for sulfur and has expanded its research efforts to utilize sulfuric acid in mineral and metal processing schemes. The current research included studies on sulfur-asphalt mixtures for paving materials; sulfur formulations for stabilizing minerals tailings piles; construction materials modified with sulfur; a new approach to phosphate production where the total ore is acidulated, thus avoiding the slimes disposal problem; and sulfuric acid leaching of limey copper ores, which cannot be beneficiated by conventional methods.

The Bureau's process for recovery of the metal and mineral content of municipal incinerator residues has received national attention which culminated in the Environmental Protection Agency awarding a $2.4 million grant to the City of Lowell, Mass., to build a 250-ton-per-day demonstration plant. The semicommercial installation will be the first of its kind in the world and will recover the ferrous, nonferrous, and glass components from several municipal incinerators in the Lowell area.

In another related approach to the urban refuse problem, a raw refuse resource recovery pilot plant was placed onstream. The new pilot plant, which has a capacity of 5 tons per hour, accepts refuse directly from municipal collection vehicles. The refuse is broken down into its metal, mineral, and energy fractions by a series of shredding, air classification, magnetic separation, and screening operations. In addition to the metal and mineral values, there is recovered a combined paper and plastic fraction which has a fuel value of over 8,000 Btu per pound.

Research is nearing completion on the combined railroad car-junk auto incinerator, which is being conducted in cooperation with a scrap processor. The incinerator allows smokeless burning of 20 scrap cars or one railroad car per hour.

Three additional smokeless scrap automobile incinerators patterned after the Bureau's prototype have been constructed, bringing to 20 the number of commercial installations. Commercial air and water elutriators, based on the Bureau's research on recovery of nonferrous metals from junk car shredder rejects, have been or are being constructed at a number of scrap yards. A cryogenic process for recovery of copper from scrap wire is also being adopted by private companies as a result of Bureau research. In cooperation with the Ford Motor Co., a process for recovery and recycle of waste polyurethane foam from scrapped automobiles has been developed.

Bureau-developed methods for stabilization of mine and mill wastes continued to be adopted by industry. A large copper company has utilized one of the Bureau's techniques to stabilize 120 acres of copper mill tailings in Nevada. During the past year the Bureau has cooperated with the Forest Service, a number of State agencies, and the private sector in developing methods for overcoming air and water pollution resulting from mineral tailings disposal in Arizona, Colorado, Michigan, Idaho, Missouri, and Washington. In a cooperative cost-sharing effort with the Florida phosphate industry, a substantial research program has been initiated to develop a practical method to dewater phosphate slimes. The study involved both basic laboratory studies and large scale field tests on the more promising dewatering schemes. Methods to dewater and dispose of a number of other mineral processing wastes such as red muds and taconite tailings were also being investigated.

Other projects related to secondary materials recovery included a variety of studies on techniques to recover and recycle values from sludges, drosses, dusts, and waste mineral processing waters. A major effort was also being made to decontaminate waste processing waters for recycle and reuse.

Coal.—Major emphasis in coal research again was placed on the production of clean-burning fuels from coal to help meet the Nation's rapidly increasing need for energy, while at the same time maintaining or improving the quality of the environment.

On the basis of a 2-year detailed study, the National Academy of Engineering's Committee on Air Quality Management Ad Hoc Panel on Evaluation of Coal Gasification Technology concluded that pilot plant work on the Bureau's SYNTHANE Process should be expedited as one of the four most important American processes for converting coal to substitute natural gas (SNG). In addition, the Academy's ad hoc panel found that the Bureau's HYDRANE hydrogasification process for SNG showed great promise and recommended further development.

During the year bituminous coal was successfully processed in the Bureau's 10-pound-per-hour HYDRANE unit. In these tests it was confirmed that strongly caking coal could be processed without first treating the coal to destroy its caking characteristics. Because up to 95% of the methane produced comes from the direct reaction of hydrogen with coal, this process offers further economic advantage over other coal gasification schemes in that a minimum amount of methanation is required to convert the gases from the gasifier to pipeline quality gas.

In other coal gasification research, strongly caking coal from the Upper Freeport seam in Preston County, W. Va., was gasified in a stirred-bed pressurized producer at 125 pounds per square inch, gage, and a side stream of the gas was processed to remove up to 98% of the H_2S. This latter step was accomplished by means of a solid absorbent consisting of 25% iron oxide and 75% fly ash.

During the year, the Bureau initiated a pilot field experiment to establish the feasibility of gasifying Western subbituminous coals in situ. Underground coal gasification could provide a major source of clean energy that would significantly reduce or eliminate many of the problems associated with conventional underground mining.

Experiments were successfully concluded in a small laboratory process development unit after showing that coal containing nearly 5% sulfur and 16% ash could be liquefied with hydrogen to yield a premium fuel oil essentially ash free and containing only 0.2% sulfur. A larger diameter reactor was constructed to study flow problems that may be encountered in a scale-up of the process.

In related research, conditions (4,000 pounds per square inch, gage, at 400°C and 2 hours residence time) were established for optimum yield of oil produced by reaction of CO and H_2O with North Dakota lignite in the absence of catalyst. Yield was found to be high at 3.2 barrels of oil per ton moisture- and ash-free lignite, or 63 weight percent, with 73 weight percent conversion of the feed.

During the year construction was undertaken on a three-stage high-temperature coal combustion pilot plant designed to produce a low-ash, high-temperature gas suitable for open-cycle MHD power generation. Research on mine waste land reclamation emphasized work on bituminous spoil and anthracite refuse banks. Bureau personnel cooperated in a pilot plant SO_2 removal study conducted at a midwestern power and light company.

Petroleum.—Laboratory-induced hydraulic fracture tests were conducted on oriented sandstone specimens whose tensile strength and permeability had been measured. Breakdown pressure and fracture orientation were determined as a function of several levels of stress, load saturation, and rate. The objective was to determine if horizontal compressive stress is always the primary factor controlling fracture orientation or if the directional properties of the rock matrix influence the induced fracture direction at low stress levels and/or low load rates.

A triaxial load cell and a closed-loop, automatic pressurization system were developed to test the specimens. Preliminary analysis has indicated that fracture orientation cannot be reliably predicted whenever the stress difference in horizontal components is less than 200 pounds per square inch. In this situation, the induced fracture direction is usually governed by permeability.

Oil and gas reservoir properties must be known to develop more efficient and economical oil and gas extraction methods. Mobility, a measure of the capacity of a reservoir rock to conduct a fluid, varies with pressure, fluid volume, liquid-gas ratio, and gas velocity. The Darcy equation is inadequate for calculating the pressure gradient needed to recover gas-condensate fluid from a reservoir at an economic rate. Suitable equations have been developed so that mobility can be computed more reliably.

The application of radiotracer pulses to the evaluation of the fracture systems of underground formations was tested in the field and in an oil shale retort having a known void matrix. Best results were achieved when the tracer was added to the flowing gas stream and sampled as near to the formation face as possible. When the pulse emerges at the production well, it has been modified by dispersion through the fracture system. The degree and rate of dispersion are used to evaluate the reservoir fracture and void systems. Nonradioactive gas tracers can be used where the presence of radioactivity might be objectionable.

Research continued on the correlation of crude oil properties. The purpose of the study is to identify the source of marine oil spills when the source is otherwsie not known. A study of the potential use of knowledge of the orientation of natural fractures in a gas storage reservoir in Eastern Ohio was completed as part of a cooperative research effort with the American Gas Association.

Numerical model studies indicated that fracture placement is important in gas-storage operations and that the composite model simultaneously determines reservoir and fracture pressure distribution. A basic two-dimensional dry-gas reservoir simulator was developed using the alternating-direction-implicit procedure. Using a relationship developed from Darcy's law to calculate the withdrawal rate of gas from any reservoir node penetrated by a fracture, the 2–D model was modified to provide the capability of simulating ideal fractures of any length and with orientation parallel to either of the finite-difference grid lines. This modified 2–D model was used to investigate the withdrawal capacity of various fracture patterns in a square reservoir. The results indicate that well and fracture placement are important in the development of a gas-storage field in which the withdrawal capacity over short periods of time is to be optimized.

An updated analysis of production tests from Project Gasbuggy over a 3-year period indicated that the flow-rate capacity of a gas well after stimulation by a nuclear explosion will be four to six times greater than if the same well were stimulated by conventional fracturing. Previous testing over a 1-year period indicated a six- to seven-fold increase in production. It is essential that the thickness-permeability product for the unaltered formation be substantial for a nuclear-stimulated method to be successful. Formation fracturing resulting from detonation of a nuclear device extends out into the formation only about 300 feet, depending on the size of the charge. Production tests and analyses for Project Rulison are being continued.

Fuels combustion research was oriented principally toward more explicitly defining the influences that fuel composition, engine adjustments, and engine-accessory devices have on pollutant emissions and on fuel economy.

Confirming evidence obtained in prior years, gasoline composition was again shown to have a significant bearing upon the photochemical reactivity of its combustion products. The light aromatics, benzene and toluene, produced relatively nonreactive products; xylenes and heavier aromatics produced moderate to highly reactive products. Highly branched alkylates were also identified as a prominent source of photochemically reactive exhaust. The principal significance of the findings was to show that there is a complex relationship between fuel composition and pollution effects, and that detailed knowledge of fuel composition is required and must be used for reliable prediction of the pollution effect.

Automobiles and truck engines equipped with emission-control devices designed toward meeting stringent pollution-control requirements were tested. Results show that emissions are markedly reduced but the requirements now projected for the mid-1970's can be met only with heavy penalties to performance and fuel economy. Because trends appear to impact adversely on energy consumption, the work in this area was redirected to emphasize improvement of fuel economy in the low-emission systems.

Gas mixtures simulating gas made from coal were found to have combustion characteristics favorable for the use of such fuel in high-efficiency engines.

Research on the toxicity hazard from diesel engines operated in underground mines was continued. Carbon monoxide and oxides of nitrogen, which present the principal toxicity problem, were found controllable at levels easily compatible with the ventilation requirements for carbon dioxide. This represents the minimum ventilation requirement possible if fuel is burned underground and combustion products are discharged into the underground environment. Significant progress was made toward the development of an adequate monitoring warning system against excessive accumulation of toxic exhaust products.

A demonstration of plugging and safe mining through an oil well penetrating the Pittsburgh coalbed in northern West Virginia was successfully accomplished. Expandable cement and a fly ash-gel-water slurry were utilized to seal the well, above and below the coalbed.

Oil Shale.—The Bureau continued its core assay program in connection with the Department's proposed oil shale leasing program. Also, samples from two cores analyzed for dawsonite content, using X-ray diffraction, expanded the knowledge of extent of deposition of this mineral. Dawsonite, of potential significance as a source of both sodium and aluminum compounds, occurs in intimate association with oil shales in the deeper deposits of the Piceance Creek Basin in Colorado. However, the extent of the mineral deposit is poorly defined. Although one core was from what is believed to be near the outer edge of the deposit, it contained a continuous dawsonite-bearing section 169 feet long. The second core, taken 6 miles west of the first, had a 680-foot continuous dawsonite section plus several shorter sections. Improved definition of these mineral deposits could have an important bearing on oil shale development and mining plans because of the potential byproduct credits.

A hydrogenated naphtha with sulfur content of less than 0.001% and nitrogen content of only seven parts per million was produced by a combination of once-through hydrocracking of crude shale oil and once-through hydrofining of the hydro-cracked naphtha. A series of catalytic reforming runs was made to evaluate this clean naphtha as a feedstock. In one such test, an 89-octane number reformate was produced from 40-octane feed with a yield of 80% by volume. This octane number of 89 is sufficiently high that the unleaded gasoline could presumably be used in a refinery pool.

Mild oxidation was shown to have potential as an economic method of preparing low-pollution shale oil fuels. In one experiment, such treatment removed about one-half of the nitrogen from naphtha.

Two new research scale oil shale retorts were placed in operation. In one, gallon-size samples of crude shale oil were prepared under closely controlled conditions to provide retort engineers with required kinetic and mechanistic data. The second was a one-half-ton retort. In the first run of this retort, a 500-pound block of shale retorted satisfactorily, reaching a maximum internal temperature of 1,090°F after 18 hours, while a bed of smaller-sized shale surrounding the block reached 1,650°F. This retort, which permits both visual and instrumental observation of the retorting shale, will provide better understanding of the environmentally-attractive in situ method of processing that is being developed.

Bureau researchers successfully used electrical resistivity surveys in the Wyoming field test area to detect two shale rubble areas that had been created underground by chemical explosives. The data were used to make estimates of the shape, height, and diameter of the two rubble zones.

Economic Analysis.—The economic research program within the Bureau of Mines continued the study of economic factors within the mineral industries as well as how the mineral industries are affected by the national economy. The purpose of this research was to provide decisionmakers with accurate information and up-to-date analyses of current conditions, to aid in making their decisions. The economic analysis program attempted to produce general methodology needed for such analysis as well as information relevant to problem solving in the field of mineral economics. Major long-term research projects undertaken included the study and forecasting of demand, supply, and productivity; financial analysis; the economics of waste recycling; input-output analysis; and the study and report of weekly price changes. Many short term economic projects were also undertaken to answer immediate questions.

Health and Safety.—A major advance in the ground control program occurred with the successful underground installation of a pumpable roof bolt, which was found to have anchorage capability exceeding that of conventional expansion-shell roof bolts. Estimated costs of installed liquid bolts compared favorably with those for conventional bolting.

A self-advancing roof shield, developed under contract and designed to protect miners in the working face area, has been delivered to the Bureau and demonstrated at the Bureau's Bruceton mine.

Water infusion tests in the Pittsburgh coalbed have shown that the techniques developed by the Bureau are effective in reducing methane emission in the face area by 50% to 80%. A semirigid, hose-type infusion packer with appropriate fittings was designed, developed, produced, and tested under a research contract.

In another contract effort, commercially available borehole packers for sealing horizontal holes in coalbeds were evaluated, and a high-pressure packer was developed that is less costly to produce and can be easily and economically repaired in the field. This is an improved tool for research on and application of techniques for methane control. An analysis of data on methane emissions from underground bituminous coal mines was undertaken. The correlations obtained to date can be used to predict the methane emission rate and assist in planning methane control procedures in bituminous coal mines.

A new generation of emergency mine communications was developed offering greater range, coverage and reliability. The system permits voice communication from the mine surface through the rail haulage carrier current trolley system and up to 500 lateral feet from the carrier system to a roving miner with a wireless personal pager. Alternate systems provide two-way voice communication between the mine surface and mining machine operators through the mine telephone system and mining equipment trailing cables and alternative communication paths through borehole power-line cables and through-the-air transmission to mine surface communications equipment. These developments will provide voice communication with all underground operating crews immediately after a disaster, permitting instructions about escape routes to be given to the miners and increasing the probability of survival and rescue.

An unmanned vehicle and three borehole devices were developed for probing mine openings during post disaster and rescue operations. A probe drill guidance system has been developed to reduce probe hole drilling time. The system will enable a drill operator to survey the bottom of the hole, calculate hole coordinates with an onsite computer, and alter the course of the drill bit, if necessary, without removing or disconnecting the drill string. The system consists of magnetic and gravity sensors, wireless data telemetry, and a remote-controlled directional drill.

A portable area lighting system and a machine-mounted lighting system utilizing circularly polarized high-pressure sodium lamps were designed and delivered under a contract to explore and develop new concepts for illumination of underground coal mines.

An underground demonstration of respirable dust suppression showed that significantly lower respirable dust levels can be maintained using a foam system as opposed to water sprays or ventilation alone. A research and development contract has resulted in the delivery of two prototype mine dust meters that provide real-time instant indication of respirable and float dust concentrations in the mine environment.

A prototype noise control system developed for a percussive drill was free from muffler icing problems and reduced the sound level from 115 to 101 decibels, permitting longer working time in the area. Prototypes of the discriminating ear protective device, which permits the wearer to hear low-level warning signals but still provides protection from sounds in excess of 90 decibels, were fabricated, tested, and found generally satisfactory.

Research and development on engine emission control of diesel-powered equipment underground had indicated that neither a water scrubber nor an oxidation catalyst has any significant effect on oxides of nitrogen emissions. The use of exhaust gas recirculation reduced NO_x, while oxidation catalysts reduced carbon monoxide levels. Continuing efforts on developing a satisfactory monitor for CO_2, CO, and NO_x have uncovered some problems in vibration stability during prolonged engine operation.

A prototype infrared methane detector was developed that can be packaged into a machine-mounted methane monitor with greater reliability than is possible with existing devices. Continued work on a nuclear technique coal dust incombustibles content analyzer has developed advanced prototype designs of both cup and in situ types of devices.

A portable device was developed for use in the field to determine whether permissible blasting machines are in operating condition. The Bureau developed a new, relatively inexpensive, and easily installed device called the horizontal roof strain indicator. Preliminary test results have indicated that 1/1000 inch per inch horizontal strain occurring within 2 days after bolt installation indicates an unstable roof condition. In other research directed at the identification of potential roof falls, it has been shown that the first major parting in a mine roof can be detected, the distance to the parting measured, and the inclination of the parting plane determined by means of sonic testing the roof with pulsed shear waves. Efforts were continuing to adapt the miscroseismic techniques, developed for detecting rock bursts in deep metal mines, for use in coal mines to prevent mining machinery noises from interfering with the detection of rock noises so that microseismic techniques can now be employed during normal mining operations. Under contract, a simple borehole device to determine the modulus of rigidity of coal-measure rocks has been developed and delivered to the Bureau. The physical properties determined by use of this device are essential to the development of rational methods of designing mine pillars and other underground structures. An evaluation into the feasibility of using isolated electrical supply systems in underground coal mines confirms that it is possible in principal to reduce fault trip currents to a level to assure personnel protection, provided that problems involving circuit breakers can be handled. A contract studying the feasibility of remote control systems and the development of remote control sensors and devices has successfully developed a laser guidance system for use in alignment of continuous miner operations as well as a shuttle car guidance system with obstruction detection capabilities. In a contract on inherently safe mining systems, nonfatal accident data were obtained and correlated with fatality data to precisely define the hazards that exist in the working sections of continuous and conventional mines. All major mining equipment manufacturers were contacted and details on the characteristics and number of units in the field were obtained. Conceptual design modifications for all equipment used in the working sections were prepared, evaluated and agreed upon.

A mineral slurry data bank, the most comprehensive compilation of hydraulic transportation data available, has been developed. An experimental pneumatic pipeline system for horizontal transport under either vacuum or pressure has been installed to determine air requirements and haulage capabilities as influenced by pipe and coal variables.

A coal mine systems simulator, which is needed for improved mine design and operational planning, and an underground coal production submodel have been developed. These provide a means for obtaining quicker and more accurate data to evaluate the effect of potential system changes on the health and safety and economics of underground coal mining operations. In metal and nonmetal mine research, a technique for nondestructively analyzing percent alpha quartz collected on field filter samples of respirable dust was developed. The ongoing contract to develop a passive personal dosimeter for nuclear radiation continued to progress with the assembly of a unit to effectively deal with radon daughter plate-out problems. Studies to determine with models the optimum configurations of different rectangular shaft timber supports, linings, and fixtures demonstrated that airway resistance could be reduced up to 25% by modifications which are relatively minor and can be readily applied in mines with severe ventilation problems.

Rock noise source location techniques for use in deep metal mines have been improved and simplified, and the necessary equipment for field application has become available at reasonable cost so that the microseismic technique is now a practical engineering tool. Closely related research on rock bursts in the Coeur d'Alene district shows that stope pillar distressing reduces the frequency and intensity of damaging bursts in the working area.

Explosives and Explosions.—A program has been initiated to develop methods of identifying the type and source of explosives from the products left after detonation. Such methods will provide improved control of explosives from two aspects—illegal explosives used in subversive activities and the use of nonpermissible explosives in gassy mines. The technique under study involves mixing phosphor-impregnated ceramic beads into the explosive formulation. These phosphor grains can be identified after detonation using ultraviolet light. Work to date on the postdetonation identification of explosives showed that suitable coated phosphors can be detected in concentrations as low as 0.02% by weight following detonation. Considerable interest has been shown by the explosives industry in the Bureau work in this area.

Two new high-density, water-gel explosives were formulated, offering an explosive strength of 120% TNT, relatively low sensitivity, and good toxic fume characteristics. These high-strength gels should gain widespread acceptance in both open pit blasting and underground noncoal mines in view of the improved fume characteristics.

An investigation was completed for the U.S. Coast Guard evaluating the causes of explosions observed during unconfined liquefied natural gas spills on water. Results indicate that the explosion hazard is real, although the amount of released energy is small. Explosions have been observed only with "weathered" liquefied natural gas (LNG) in which the methane content has been reduced significantly. Layering and downwind spread of flammable vapors are significant hazards.

A definitive test for the incendivity of detonators was developed and a number of detonators checked to ascertain the risk of methane-air ignition. A detonator design is not considered acceptable if two detonators fired simultaneously will ignite a methane-air mixture. Certain types of detonators in current use have been identified as especially hazardous because a single detonator will cause ignition.

LEGISLATION AND GOVERNMENT PROGRAMS

During 1972 the President continued the Phase II controls, which were begun at the end of the 90-day freeze of Phase I. Phase II was based on voluntary support; it was geared to encourage the expansion of output and employment; and it was a temporary program.

Phase II relaxed the Phase I controls. Some pay increases greater than 5.5% were allowed, and price increases were handled on a firm-by-firm basis. Within the controlled area, firms and bargaining units were divided into three groups. Large firms were required to give advance notice of price or wage increases; those in the middle group were not required to give advance notice unless they requested an exception, but they were required to file reports of increases; the third group, which consisted of the smallest units, was not required to file reports, but their actions were open to spot checks. Phase II with modifications continued through 1972.

Legislation affecting the mineral sector and approved during the second session of the 92d Congress covered such areas as the environment, water, public land, black-lung disease benefits, pipeline safety, consumer safety, the price of gold, the strategic stockpile and a few other areas.

The environment was the concern of several laws. Public Law 92-500, Water Pollution Control, was passed over a Presidential veto. To be administered by the Environmental Protection Agency (EPA), it provided money for acid mine water pollution control projects; required the use of the best practicable control technology for waste discharges by July 1, 1977; and the use of the best available control technology by July 1, 1983. It also transferred the discharge permit program under the Refuse Act from the Corps of Engineers to EPA. Public Law 92–574, Proposed Environmental Noise Control Act of 1972, was passed by Congress on October 18, and signed into law by the President on October 27. It required the EPA administrator to develop and publish criteria for noise; he was also given the responsibility for establishing noise emission standards. Public Law 92–307, Interim Operating Licenses for Nuclear Power Plants, amended the Atomic Energy Act of 1954 to authorize the Atomic Energy Commission (AEC) to issue temporary operating licenses for nuclear power reactors to avoid severe power shortages, provided adequate protection for the environment is assured.

Other measures approved which may be of interest to the mineral industries included Public Law 92–287, which established a Bureau of Mines metallurgy research center on the Fort Douglas Military Reservation in Utah to replace the one on the University of Utah Campus; and Public Law 92–285, Public Law 92–355, and Public Law 92–356, which authorized disposal from the national stockpile of zinc, nickel and lead. A listing of mineral related Federal legislation signed into law during 1972 follows:

Public Law (P.L.) and description	Signed into law
Environmental quality:	
P.L. 92–307.—Authorizing AEC to issue temporary operating licenses for nuclear power reactors.	June 2
P.L. 92–500.—Proposed Federal Water Pollution Control Act Amendments of 1972.	Oct. 18
P.L. 92–532.—To ban the unregulated dumping of materials into the oceans, estuaries, and Great Lakes.	Oct. 23
P.L. 92–574.—Proposed Environmental Noise Control Act of 1972.	Oct. 27
P.L. 92–583.—Authorizing funds for fiscal year 1973 to assist States in establishing and administering coastal zone and estuarine management programs.	Oct. 27
Water resources:	
P.L. 92–273.—Authorizing $26.8 million for the saline water conversion program for fiscal year 1973.	April 17
P.L. 92–396.—To increase authorizations for activities of the Water Resources Council.	Aug. 20
P.L. 92–577.—Authorizing the Secretary of the Interior to engage in feasibility investigations of certain potential water resource developments.	Oct. 27
Public lands:	
P.L. 92–230.—To designate Pine Mountain Wilderness within and as a part of Prescott and Tonto National Forests, Arizona.	Feb. 15
P.L. 92–241.—To designate Sycamore Canyon Wilderness, the Coconino, Kalibab, and Prescott National Forests, Arizona.	Mar. 6
P.L. 92–395.—To designate as wilderness national forest lands known as the Lincoln Back Country and parts of the Lewis and Clark and Lolo National Forests in Montana.	Aug. 20
P.L. 92–400.—To establish the Sawtooth National Recreation Area in Idaho.	Aug. 22
Indian lands:	
P.L. 92–431.—To authorize longer term leases of Indian lands located outside the boundaries of Indian reservations in New Mexico.	Sept. 26
National stockpile:	
P.L. 92–283.—Authorizing the disposal of 515,200 short tons of zinc from the national stockpile.	April 26
P.L. 92–355.—Authorizing the disposal of nickel from the national stockpile.	July 26
P.L. 92–356.—Authorizing the disposal of lead from the national stockpile and supplemental stockpile.	July 26
Health and safety:	
P.L. 92–303.—To amend the Federal Coal Mine Health and Safety Act so as to extend black-lung benefits to orphans whose fathers died of pneumoconiosis.	May 19
P.L. 92–401.—Extending time in which States may certify that their laws conform to the Natural Gas Pipelines Safety Act.	Aug. 22
P.L. 92–573.—To protect consumers against unreasonable risk of injury from hazardous products.	Oct. 27
Gold and medallions:	
P.L. 92–228.—To provide for the striking of medals in commemoration of the bicentennial of American independence.	Feb. 15
P.L. 92–268.—Increasing from $35 to $38 per ounce the price of gold, thus modifying the par value of the dollar.	Mar. 31

Public Law (P.L.) and description	Signed into law
Miscellaneous:	
P.L. 92–287.—To establish a metallurgy research center on the Fort Douglas Military Reservation, Utah, and convey certain lands to the University of Utah.	May 1
P.L. 92–322.—Granting congressional consent to a 3-year extension of interstate compact to conserve oil and gas.	June 30
P.L. 92–325.—Extending the Defense Production Act for two additional years through fiscal year 1974.	June 30

The acquisition cost of strategic materials in government inventories totaled $5.9 billion with a market value of $6.7 billion as of December 31, 1972. Materials in these government inventories with a market value of $2.7 billion were considered in excess of stockpile needs. In calendar year 1972, the Government disposed of $289 million worth of mineral commodities, a 23% increase from the 1971 figure. Major mineral stockpile items sold during the year with a sales value of at least $10 million each included cobalt, industrial diamonds, lead, and metallurgical manganese. Sales of nickel had a value greater than $100 million, and zinc sales were greater than $60 million.

WORLD REVIEW

World Economy.—The long-run growth in world trade continued through 1972, despite conditions that necessitated governmental actions concerning exchange rates and capital movements. Exchange rates during the year were governed by the Smithsonian agreement, which was a set of "central" rates set up just before the beginning of the year to replace the pattern of floating exchange rates that came into being after the United States suspended the convertibility of the dollar in August 1971. The central rates provided an effective revaluation of major currencies. The foreign exchange markets were calmer during the later part of the year.

Inflation continued to be a major world economic problem during 1972. The countries of the European Economic Community (EEC), concerned about inflation, agreed to a program of coordinated anti-inflationary efforts.

Moderate economic growth continued to be the pattern for most developed countries. Canada had an increase in industrial production of 6.7%; the increase for Japan was 6.8%. Spain had a notably large increase in industrial production of 17.6%.

World Production.—The United Nations (UN) indexes of world mineral industry production (1963 = 100) for the extractive industries increased 4 index points to 155 in 1972. In the metals category world production remained constant. There were increases in the metal production of Communist Europe and decreases in the non-Communist world. The total output of coal declined two points to 103 during 1972. The non-Communist world declined in coal production, although the United States-Canada and the Australia-New Zealand coal production indexes increased significantly. Coal production in Communist Europe increased slightly. World production of crude petroleum and natural gas increased 7 index points to 184. All areas increased their output with the exception of Latin America, which declined 6 index points to 112. Overall industrial production as measured by the UN index rose 11 points to 176 during 1972. It should be noted that, this year, more countries are included in the EEC and fewer in the European Free Trade Association than in previous years. Denmark, Ireland and the United Kingdom recently joined the EEC and are now included in these indexes. Denmark and the United Kingdom are no longer included under the European Free Trade Association.

World Trade.—The value of world trade in all commodities increased almost 12% to $348.1 billion in 1971. Exports of mineral commodities increased more than 8% to $73.9 billion. During 1971 metal exports declined over 4% to $35.6 billion. This is only 48% of the mineral commodity trade. In the past, metals have usually accounted for more than 50% of this trade. Within the metals group, all ores, concentrates, and scrap exports declined 8%, iron and steel exports increased almost 5%, and nonferrous metals exports declined almost 15%. Nonmetal exports increased almost

5% to $2.5 billion. World trade in mineral fuels increased 25% to $35.8 billion. This is larger by $0.2 billion than metal exports, which in the past accounted for the largest share of this trade.

World Prices.—The mineral commodity export price indexes (1963=100) for fuels and all crude minerals increased 12.6% and 11.0% respectively, while that for metal ores increased only 6.3% during 1972.

The price index for metals increased 8 index points to 134. The index for fuels increased 16 index points to 143 and that for all crude minerals increased 14 index points to 141. Total minerals prices increased significantly in both developed and developing areas. Nonferrous base metal prices remained nearly constant, declining 1 index point in developed areas and increasing 1 index point in developing areas.

Table 1.—Value of mineral production,[1] exports, and imports, by group

(Million dollars)

1972 p	181	14,350	24,878	19,344	2,893	576	62,222

p Preliminary. r Revised.

[1] Heat values employed for bituminous coal and lignite are: 1968, 12,530 Btu per pound; 1969, 12,450 Btu; 1970, 12,290 Btu; 1971, 12,120 Btu; and 1972, 12,120 Btu.

[2] Heat values employed for crude petroleum are: 1968, 5,585,016 Btu per barrel; 1969, 5,601,070 Btu; 1970, 5,620,900 Btu; 1971, 5,594,100; and 1972, 5,598,100 Btu.

[3] Hydropower and nuclear power include installations owned by manufacturing plants and mines as well as government and privately owned public utilities. The fuel equivalent of hydropower and nuclear power is calculated from the kilowatt-hours produced, converted to theoretical energy resources inputs calculated from national average heat rates for fossil-fueled steam electric plants provided by the Federal Power Commission using 10,398 Btu per net kilowatt-hour in 1968; 10,447 Btu in 1969, and 10,494 Btu in 1970. Energy inputs for hydropower in 1971 and 1972 are converted at an average heat rate of 10,478 Btu per net kilowatt-hour generated. Energy inputs for nuclear power in 1971 and 1972 are converted at an average heat rate of 10,660 Btu per net kilowatt-hour based on information from the Atomic Energy Commission.

r Revised. p Preliminary.

[1] Heat values employed are: anthracite, 12,700 Btu per pound and bituminous coal and lignite, weighted average Btu provided by the Division of Fossil Fuels, Branch of Coal, 12,430 Btu per pound in 1968; 12,380 Btu per pound in 1969; 12,110 Btu per pound in 1970; and 11,980 Btu per pound in 1971 and 1972. Weighted average Btu for petroleum products obtained by using 5,248,000 Btu per barrel for gasoline and naphtha-type jet fuel, 5,670,000 for kerosine and kerosine-type jet fuel; 5,825,000 for distillate; 6,287,000 residual; 6,064,800 for lubricants; 5,537,280 for wax; 6,636,000 for asphalt; and 5,796,000 for miscellaneous. Natural gas dry, 1,032 Btu in 1968 and 1,031 Btu per cubic foot thereafter; natural gas liquids weighted average Btu; natural gasoline and cycle products, 110,000 Btu per gallon; LP-gases 95,000 per gallon; and ethane 73,390 Btu per gallon. Hydropower (adjusted for net imports or net exports) and nuclear power are derived from net electricity generated, converted to theoretical energy resources inputs calculated from national average heat rates for fossil-fueled steam-electric plants provided by the Federal Power Commission using 10,398 Btu per net kilowatt-hour in 1968; 10,447 Btu in 1969, and 10,494 Btu in 1970. Energy inputs for hydropower in 1971 and 1972 are converted at an average heat rate of 10,478 Btu per net kilowatt-hour generated. Energy inputs for nuclear power in 1971 and 1972 are converted at an average heat rate of 10,660 Btu per net kilowatt-hour based on information from the Atomic Energy Commission.

p Preliminary. r Revised. NA Not available.

[1] Excludes natural gas liquids.

[2] Petroleum products including still gas, liquefied refining gas (LRG), and natural gas liquids.

[3] Represents outputs of hydropower (adjusted for net imports or net exports) and nuclear power converted to theoretical energy inputs calculated from national average heat rates for fossil-fueled steam-electric plants provided by the Federal Power Commission using 10,898 Btu per net kilowatt-hour in 1968; 10,447 Btu in 1969; and 10,494 in 1970. Energy inputs for hydropower in 1971 and 1972 are converted at an average heat rate of 10,478 Btu per net kilowatt-hour generated. Energy inputs for nuclear power in 1971 and 1972 are converted at an average heat rate 10,660 Btu per net kilowatt-hour based on information from the Atomic Energy Commission. Excludes inputs for power generated by nonutility fuel-burning plants which are included within the other consuming sectors.

[4] Gross energy is that contained in all types of commercial energy at time it is incorporated in the economy, whether energy is produced domestically or imported. Gross energy comprises inputs of primary fuels (or the derivatives) and outputs of hydropower and nuclear power converted to theoretical energy inputs. Gross energy includes energy used for production, processing, and transportation of energy proper.

[5] Utility electricity, generated and imported, distributed to the other consuming sectors as energy resource inputs. Distribution to sectors is based on historical series in the Edison Electric Institute Yearbook. Conversion of electricity to energy equivalent by sectors was made at the value of contained energy corresponding to 100% efficiency using a theoretical rate of 3,412 Btu per kilowatt-hour.

[6] Energy resource inputs by sector, including direct fuels and electricity distributed.

[7] Includes bunkers and military transportation.

[8] Data may not add to totals shown because of independent rounding.

p Preliminary. NA Not available.

[1] Includes use by producers for power and heat.

[2] Includes shipments to U.S. Armed Forces in West Germany.

[3] Except for small quantities used as raw material for coal chemicals, all anthracite is used for fuel and power.

[4] Data represent "retail deliveries to other consumers." These are mainly household and commercial users, with some unknown portion of use by small industries.

[5] Includes consumption by coke plants, steel and rolling mills, and other industrial uses.

[6] Includes bunkers and military transportation.

[7] Data not available. Believed to be small and of minor significance.

[8] Figures in parentheses are not added into totals.

[9] Coal equivalent based on Btu value of raw materials used for coal chemicals.

p Preliminary.

[1] Marketed production includes wet gas sold or consumed by producers, losses in transmission, producers' additions to storage, and increases in gas pipeline fill; excludes repressuring and quantities vented and flared. Btu value of production is for wet gas prior to extraction of natural gas liquids. Higher Btu values assigned to extraction loss are reflected in value of natural gas liquids production for each year.

[2] Extraction loss from cycling plants represents offtake of natural gas for natural gas liquids as reported to the Bureau of Mines. Energy equivalent of extraction loss is based on annual outputs of natural gasoline and associated products at 110,000 Btu per gallon, annual outputs of LPG at 95,500 Btu per gallon, and annual outputs of ethane at 73,890 Btu per gallon. (Prior to 1967, ethane production was included with LPG in converting to Btu values.)

[3] Includes transmission losses of 338,999 million cubic feet in 1971 and 328,002 million cubic feet in 1972.

[4] Includes some fuel and power used by raw material industries.

[5] Estimated from partial data.

Note: Conversion factor for dry gas is 1,031 Btu per cubic foot.

[p] Preliminary.

[1] Supply and demand for crude oil and petroleum products. Petroleum products include products refined and processed from crude oil, including still gas and LRG; also natural gas liquids transferred from natural gas.

[2] Btu value for crude oil for each year shown is based on average Btu value of total output of petroleum products (including refinery fuel and losses) adjusted to exclude natural gas liquids inputs and their implicitly derived values. Value for net imports or crude is based on the average value of crude runs to stills.

[3] Includes some Athabasca hydrocarbons.

[4] Btu values for natural gas liquids for each year shown are implicitly derived from weighted averages of production of major natural gas liquids, derived by converting natural gasoline and cycle products at 110,000 Btu per gallon, LPG at 95,000 Btu per gallon, and ethane at 73,390 Btu per gallon.

[5] Includes natural gas liquids other than those channeled into refinery input as follows: petrochemical feedstocks, direct uses for fuel and power, and other uses.

[6] Includes bunkers and military transportation.

[7] Includes some fuel and power used by raw materials industries.

1972 p	95	93	85	135	101	87	121

p Preliminary.
[1] Excludes fuels.

Table 17.—Physical stocks of mineral energy resources and related products at yearend

(Producers' stocks, unless otherwise indicated)

Fuels	1968	1969	1970	1971	1972 p
Coal and related products:[1]					
Bituminous coal and lignite [2] short tons	85,525,000	80,482,000	92,275,000	89,985,000	115,313,000
Coke do	5,985,025	3,120,000	4,113,000	3,510,000	2,914,000
Petroleum and related products:					
Carbon black thousand pounds	224,170	208,020	296,087	296,028	237,695
Crude petroleum and petroleum products thousand barrels	997,572	980,123	1,017,861	1,043,947	958,979
Crude petroleum do	272,193	265,227	276,367	259,648	246,395
Natural gas liquids do	([3])	([3])	([3])	([3])	([3])
Natural gasoline, plant condensates, and isopentane do	5,466	5,704	7,046	6,176	6,075
Gasoline do	211,526	217,392	214,348	223,771	217,149
Special naphthas do	5,829	6,292	6,193	5,384	5,232
Liquefied gases [4] do	76,160	59,602	67,043	94,713	85,717
Distillate fuel oil do	173,158	171,714	195,271	190,622	154,319
Residual fuel oil do	67,359	58,395	53,994	59,681	55,216
Petroleum asphalt do	20,055	16,753	15,779	21,202	21,636
Other products do	165,826	179,044	181,820	182,750	167,240
Natural gas [5] billion cubic feet	2,746	2,852	3,207	3,523	3,523

p Preliminary.
[1] Series on anthracite stocks in ground storage has been discontinued.
[2] Stocks at industrial, consumer, and retail yards and on upper lake docks.
[3] Now distributed among petroleum products shown below.
[4] Includes ethane.
[5] American Gas Association.

Table 18.—Seasonally adjusted book value of product inventories for selected mineral processing industries

(Million dollars)

End of year or month	Petroleum and coal products	Stone, clay, and glass products	Primary metals: Blast furnace and steel mills	Primary metals: Other primary metals [1]	Primary metals: Total
1968: December	2,118	2,219	4,039	3,513	7,552
1969: December	2,274	2,483	4,312	3,740	8,052
1970: December	2,539	2,648	4,717	4,145	8,862
1971: December	2,433	2,263	4,800	4,395	9,195
1972:					
December	2,200	2,381	5,244	4,375	9,619
January	2,235	2,257	5,062	4,266	9,328
February	2,215	2,253	5,123	4,273	9,396

Table 19.—Value of selected minerals and mineral products imported and exported by the United States in 1972, by commodity group, and commodity[1]

(Thousand dollars)

SITC code[2]		Exports	Imports
	Minerals, nonmetallic (crude):		
271	Fertilizers, crude	108,687	7,082
273	Stone, sand and gravel	18,646	27,899
274	Sulfur and unroasted iron pyrites	32,499	16,760
275	Natural abrasives (including industrial diamond)	39,624	54,540
276	Other crude minerals	144,973	191,365
	Total	344,379	297,646
	Metals (crude and scrap):		
281	Iron ore and concentrates	26,775	415,934
282	Iron and steel scrap	243,608	17,666
283	Ores and concentrates of nonferrous base metals	105,263	471,915
284	Nonferrous metal scrap	120,466	58,916
285	Platinum and platinum-group metal ores and concentrates	11,180	26,618
286	Uranium and thorium ores and concentrates	627	89
	Total[3]	507,920	991,138
	Mineral energy resources and related products:		
321	Coal, coke, and briquets (including peat)	1,019,116	22,609
331	Petroleum, crude and partly refined	2,651	2,592,607
332	Petroleum products, except chemicals	442,361	1,722,159
341	Gas, natural and manufactured	89,720	476,700
	Total[3]	1,553,847	4,814,075
	Chemicals:		
	Inorganic chemicals:		
513	Elements, oxides, and halogen salts	262,087	348,696
514	Other inorganic chemicals	152,054	74,082
515	Radioactive and associated materials except uranium and thorium	181,332	110,104
521	Mineral tar, crude chemicals from coal, petroleum, and natural gas	30,855	7,959
	Total	626,328	540,841
	Minerals, nonmetallic (manufactured):		
661	Lime, cement, and fabricated building material, except glass and clays	17,814	112,692
662	Clays and refractory construction materials	66,121	60,688
663	Mineral manufactures, not elsewhere specified	89,644	47,846
	Total	173,579	221,226
	Metals (manufactured):		
671	Pig iron, spiegeleisen, sponge iron, iron and steel powder and shot, and ferroalloys	26,213	184,684
672	Iron or steel ingots and other primary forms	52,093	38,351
673	Iron or steel bars, rods, angles, shapes, and sections	88,799	705,515
674	Iron or steel universals, plates, or sheets	183,780	1,397,474
675	Iron or steel hoops and strips	76,146	63,228
676	Iron or steel rails and railway track construction materials	20,447	6,406
677	Iron or steel wire (excluding wire rod)	16,409	142,206
678	Iron or steel tubes, pipes, and fittings	247,409	379,374
679	Iron or steel castings or forgings, unworked	114,565	14,396
681	Silver, platinum, and platinum-group metals	92,828	178,661
682	Copper and copper alloys	247,832	427,425
683	Nickel and nickel alloys	47,919	349,810
684	Aluminum and aluminum alloys	196,201	374,093
685	Lead and lead alloys	4,501	64,751
686	Zinc and zinc alloys	5,928	181,227
687	Tin and tin alloys	3,868	199,685
688	Uranium and thorium metals and alloys	291	(4)
689	Miscellaneous nonferrous base metals	60,562	73,558
	Total	1,485,791	4,780,839
	Grand Total	4,691,844	11,645,765

---

Table 22.—Consumption of major mineral products, mineral fuels, and electricity 1971, 1972, and projections

Commodity	1971	1972 p	2000
MINERAL PRODUCTS			
Ferrous metals:			
Iron ore ... thousand long tons	116,196	126,948	NA
Iron content ... million short tons	75	NA	158
Raw steel (production) ... thousand short tons	120,443	133,241	NA
Chromite ores (gross weight):			
Metallurgical grade ... do	720	727	NA
Refractory grade ... do	193	224	NA
Chemical grade ... do	180	189	NA
Manganese ore (35% or more Mn) ... do	2,155	2,331	3,900
Molybdenum (Mo content) ... thousand pounds	40,950	45,558	188,000
Tungsten (W content) ... do	11,622	14,107	76,400
Nonferrous metals:			
Aluminum (apparent consumption) ... thousand short tons	5,099	5,588	28,400
Antimony, primary ... short tons	13,707	16,124	48,000
Copper, refined ... thousand short tons	2,020	2,239	7,100
Lead, primary and secondary ... do	1,482	1,485	2,730
Zinc, all classes ... do	1,651	1,829	3,090
Mercury, primary ... 76-pound flasks	52,257	52,907	102,000
Platinum-group metals ... thousand troy ounces	1,266	1,560	3,157
Silver (industrial consumption) ... do	129,146	151,063	420,000
Ilmenite and titanium slag (estimated TiO_2 content) ... short tons	588,072	649,025	1,840,000
Uranium (U_3O_8, estimated purchases by private industry) ... do	12,800	11,600	73,118
Nonmetals:			
Asbestos (apparent consumption) ... thousand short tons	759	809	2,430
Cement (production) ... do	78	85	NA
Clays (apparent consumption) ... do	[1] 56,666	59,456	174,000
Lime (sold or used) ... do	19,591	20,290	NA
Phosphate rock (P_2O_5 content, apparent consumption) ... do	12,553	13,753	NA
Potash (K_2O content, apparent consumption) ... do	4,794	4,814	14,455
Salt (apparent consumption) ... do	47,262	47,618	158,900
Sand and gravel ... million short tons	920	918	3,200
Stone, crushed (sold or used) ... do	874	923	3,400
Sulfur, all forms (apparent consumption) ... thousand long tons	9,173	9,833	30,000
MINERAL ENERGY RESOURCES AND ELECTRICITY			
Bituminous coal ... million short tons	495	520	1,000
Coal carbonized for coke [2] ... do	(83)	(87)	(115)
Anthracite ... do	7	6	2
Petroleum production and natural gas liquids ... million barrels	5,553	5,990	14,500
Natural gas, dry [3] ... million cubic feet	22,132	22,429	49,000
Electricity generation, net ... million kilowatt hours	1,717,520	1,853,390	NA
Utilities ... do	1,613,936	1,747,823	[4] 9,010,000
Hydropower [5] ... do	269,851	280,285	[4] 700,000
Nuclear power ... do	37,899	54,031	[4] 5,470,000
Conventional fuel-burning plants ... do	1,309,716	1,420,558	[4] 2,840,000
Industrial ... do	103,585	106,067	NA
Total energy resources inputs ... trillion Btu	68,698	72,242	[4] 191,900

p Preliminary. NA Not available.

[1] Erroneously omitted in 1971 table.

[2] Figures in parentheses are not added to totals.

[3] Residue gas excludes extraction loss but includes transmission loss.

[4] Dupree, Walter G. Jr., and James A. West. U.S. Energy Through Year 2000. U.S. Department of the Interior. December 1972. Tables 1 and 8.

[5] Net generation adjusted for net imports or exports. The bulk of net trade is hydropower with an undetermined amount of steam plant power.

Table 32.—Comparative mineral energy resource prices

Fuel		1970	1971	1972
Bituminous coal average prices, cost of coal at merchant coke ovens	dollars per net ton	12.28	15.32	17.67
Anthracite, average sales realization per net ton at preparation plants, excluding dredge coal:				
Chestnut	dollars	15.67	16.79	17.66
Pea	do	13.87	15.28	15.72
Buckwheat, No. 1	do	13.26	14.83	15.38
Petroleum and petroleum products:				
Crude petroleum, average price per barrel at well	do	3.18	3.39	3.39
Gasoline, average dealers' net price (excluding taxes) of gasoline in 55 U.S. cities [1]	cents per gallon	17.68	18.11	17.72
Residual fuel oil:				
No. 6 fuel, maximum 1% sulfur, at Philadelphia [1]	dollars per barrel (refinery)	3.16	4.21	4.05
Bunker C, average price for all Gulf ports [1]	do	2.44	2.81	2.05
Distillate fuel oil:				
No. 2 distillate, average of high and low prices at Philadelphia [1]	cents per gallon (refinery)	11.08	11.78	11.75
No. 2 distillate, average price for all Gulf ports [1]	do	9.41	9.80	10.10
Natural gas:				
Average U.S. value at well	cents per thousand cubic feet	17.1	18.2	18.6
Average U.S. value at point of consumption	do	53.6	57.7	62.1

p Preliminary. r Revised NA Not available.

[1] Index of labor costs per unit of output: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based upon net tons per man per day (see chapter on Bituminous Coal) and index of average earnings derived from Bureau of Labor Statistics data on hourly earnings; petroleum index based on barrels per year (see chapter on Petroleum) and Bureau of Employment Security data on total wages in petroleum production.

Index of value of product per man-period: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based on net tons per man per day and mine value of production; petroleum index based on average employment and total value of production.

Index of labor costs per dollar of product: Iron ore and copper indexes are computed from data found in U.S. Department of Labor, Employment and Earnings and Wholesale Price Indexes. Bituminous coal index based on index of value per man per day and index of average earnings; petroleum index based on total value of production and total wages.

[2] Indexes are for recoverable metal.

Table 57.—Summary of government inventories of strategic and critical materials, December 31, 1972

	Acquisition cost	Market value[1]
Total inventories in storage:		
National stockpile	$3,947,856,000	$4,893,774,300
Supplemental stockpile	1,359,907,600	1,438,417,100
Defense Production Act	649,171,400	362,112,800
Commodity Credit Corporation	--	--
Total on hand	5,956,935,000	6,694,304,200
On order:		
Inventories within objective:		
Total on hand	3,288,522,500	4,023,742,100
Inventories excess to objective:		
Total on hand	2,668,412,500	2,670,562,100

[1] Market values are computed from prices at which similar materials are being traded; or in the absence of current trading, at an estimate of the price which would prevail in commercial markets. Prices used are unadjusted for normal premiums and discounts relating to contained qualities, or for inherent materials-handling allowances. Market values do not necessarily reflect the amount that would be realized at time of sale. The uncommitted excess excludes the unshipped sales; the inventories in storage include quantities that have been sold but not shipped.

[1] Data presented are for selected major commodity groups of the Standard International Trade Classification—Revised (SITC—R) and as such exclude some mineral commodities classified in that data array together with other (nonmineral) commodities. SITC—R categories included are as follows: ores, concentrates and scrap—SITC Division 28; iron and steel—SITC Division 67; nonferrous metals—SITC Division 68; nonmetals (crude only)—SITC Division 27; mineral fuels—SITC Section 3. Major items not included are the metals, metalloids, and metal oxides of SITC Group 513; mineral tar and crude chemicals from coal, petroleum, and natural gas of SITC Division 52; manufactured fertilizers of SITC Division 56; and nonmetallic mineral manufactures of SITC Groups 661, 662, 663, and 667.

Technologic Trends in the Mineral Industries (Metals and Nonmetals Except Fuels)

By John L. Morning [1]

Environmental considerations, reduced ore grades, and the related increased quantities of material handled were the dominant concerns of the minerals industry in 1972.[2] As in recent years, the basic problem facing the domestic mineral industries was the widening gap between domestic demand and domestic production, a gap which has gradually developed since 1950.[3] Development of indigenous mineral resources faced the problem of increased costs to meet environmental regulations and health and safety standards. Environment factors continued to draw priorities as they became an integral part of mine and plant design. As of July 1972, 29 States had enacted surface mined area, environmental protection legislation. Generally, these laws required operators to prepare reclamation plans, obtain permits, and post performance bonds.

Despite these problems, the growth of the minerals industry (metals and nonmetals except fuels) in 1972 recovered from the downturn in 1971. Crude ore production rose 60 million tons, a 2% increase compared with that of 1971, to nearly 2.7 billion tons. Total value of metals and nonmetals output rose to $10.133 billion from $9.461 billion in 1971. In terms of 1972 constant dollars, value of mineral products has grown at an annual growth rate of 1.8% annually since 1963.

Nearly 4.2 billion tons of material was handled in 1972 compared with 2.9 billion tons in 1963 and 3.6 billion tons in 1968.

The downward trend in exploration and development activity continued for the third straight year primarily because of reduced activity at uranium operations. However, copper, gold, asbestos, and fluorspar operations reported significantly increased activity.

Materials Handled.—Total material handled at metal and nonmetal mines and quarries in the United States rose to nearly 4.2 billion tons in 1972, an increase of 2% compared with that of 1971. Table 1 shows data for the 13-year period of 1960 to 1972, which indicates that total material handled has grown at an annual rate of 3.2%. Most of the growth has occurred in the quantity of crude nonmetal ores produced and in the waste material handled at surface metal mines. Underground mining has been relatively stable, particularly for metal mines.

Crude ore output in 1972 totaled nearly 2.7 billion tons, 60 million tons higher than in 1971, but 10 million tons lower than in 1970 the record year. Although metal mines accounted for the minor portion of the total, the trend in the past 10 years has been to an increased share of the total crude ore output, which rose from 20% in 1963 to 22% in 1972. Copper and iron ore accounted for 83% of metal mine crude ore output, whereas phosphate rock, sand and gravel, and stone accounted for 93% of the nonmetal crude ore production. For comparison, the percentages for the same commodities in 1963 were 74% and 93%, respectively, and in 1968, 81% and 91%, respectively.

Waste material accounted for over one-third of total material handled in the minerals industry, rising to over 1.5 billion tons during the year. A large portion of the total came from stripping activities in copper, iron ore, uranium, and phosphate rock. For metal mines, copper led in both crude ore production and waste material handled, and for nonmetal operations, stone led in crude ore production and phosphate rock in waste material handled.

[3] Secretary of the Interior. First Annual Report of the Secretary of the Interior Under the Mining and Minerals Policy Act of 1970 (P.L. 91–631). March 1972, 142 pp.

Eleven States (Arizona, California, Florida, Michigan, Minnesota, Montana, Nevada, New Mexico, Texas, Utah, and Wyoming) compared with 10 in 1971 handled more than 100 million tons of material. Illinois was dropped from the list, while Montana and Nevada were added. Three States reported handling between 90 and 100 million tons of material. Arizona and Florida led the nation in both total material handled and crude ore output; both States produced over 200 million tons of crude ore. Arizona and Florida have led the nation in total materials handled since 1965.

Magnitude of the Mining Industry.—Crude ore production was reported from 13,723 mines and quarries. The data are comparable with 1971 but are not comparable with other years owing to elimination from the data of brine and pumping operations. Of the total mines reporting production, clay mines totaled 1,064; sand and gravel operations, 6,690; crushed and broken stone operations, 4,448; dimension stone operations, 391; other nonmetal mines, 531; and metal mines, 599. In addition, there were 103 wells, ponds, or pumping operations.

Excluding clay, sand and gravel, and stone operations, a total of 1,130 metal and nonmetal mines reported production of crude ore or waste compared with 1,299 mines in 1971. Most of the decrease was accounted for by small mines producing less than 10,000 tons of crude ore annually. In metal mining, lead and zinc and uranium mines decreased in number primarily because of the soft market for lead and zinc and the lack of markets for uranium. Both placer gold and silver mines showed an increase in number owing to increased prices of these precious metals. The number of mines also decreased for most nonmetals. Small feldspar mines decreased owing to competition from larger more economical mines. Phosphate rock mines decreased by 10 owing to changes in statistical counting.

Crude ore production ranged from less than 1 ton of ore to nearly 37 million tons while total material handled ranged to nearly 125 million tons.

The 25 leading metal mines produced nearly 384 million tons of crude ore, 8% higher than the figure for 1971, and accounted for 67% of the total output of crude ore from metal mines. The same mines also handled 1,147 million tons of material, an increase of 9% over that of 1971, and represented 69% of the total material handled at metal mines.

The 25 leading nonmetal mines produced 169 million tons of crude ore and handled 409 million tons of material. This production represented 8% and 16% respectively, of total crude ore and total material handled at nonmetal mines.

Value of Principal Mineral Products.—When possible, the measurement of value used in table 4 is mine output, the form in which the minerals are extracted from the ground. For some commodities, the value is of beneficiated products. Values for some metals are assigned according to the average selling price of refined metal.

Value patterns for most mineral commodities rose in 1972 after suffering a decline in 1971, but a few commodities remained unchanged and a few declined in value. Unit values for ore at underground mines were generally higher than those from surface mining.

The contribution of byproducts to the value of ore continued to be more significant to the output of metal ores than to that of nonmetal ores. Byproducts accounted for 8% of value of metal ores and 1% of nonmetal ores. Excluding the large volume commodities of stone and sand and gravel, byproducts contributed 7% to the value of combined metal and nonmetal ores and 3% to nonmetal ores. Byproducts enhanced the value of ores of lead 28%, silver 20%, zinc 20%, fluorspar 13%, feldspar 11%, and mica (scrap) 8%.

Comparison of Production From Surface and Underground Mines.—Surface mining continued to account for 94% of all crude ore production and 96% of total material handled. Although there is little variation in the year-to-year ratio of production from surface and underground mines, the long-term trend indicates an increasing percentage of material mined by surface methods. In 1963, surface mining accounted for 93% of crude ore production and 95% of total material handled. The biggest change between the comparison years was in metal mining as the percentage of surface crude ore production increased from 82% in 1963 to 85% in 1972, and total material handled rose from 91% to 95%. Most metal commodities during the 10-year span especially copper, lode gold, and iron ore indicated higher percentages mined by surface methods, however silver and zinc showed a reversal of the trend.

Nonmetal mining statistics are dominated by the large volume commodities—clay, phosphate rock, sand and gravel, and stone—which are primarily mined by surface methods. Therefore, over the years of this survey no discernable trend has been evident in the totals for nonmetal commodities. Over the 10-year period, production of fluorspar, gypsum, and vermiculite crude ore mined by surface methods has increased.

Two metal commodities, antimony and lead, and three nonmetal commodities, potassium salts, sodium carbonate, and wollastonite were mined entirely by underground methods.

Ratio of Ore Treated to Marketable Product.—The ratio of ore treated to marketable product—that is, the amount of ore that must be processed to produce a given amount of marketable material—varies with the mineral commodity; a low ratio is, of course, desirable. The ratio ultimately depends on the grade of ore treated and the type of valuable mineral content; for example, in the last decade the ratios for copper and iron have risen, indicating that lower grade ores are being processed. For copper, the average grade of ore has declined so that more ore must be processed per unit of product; for iron, new technology has enabled iron ore pellets of higher iron content to be produced, thus effectively upgrading the ore and increasing the ratio.

Over the last 10 years, the ratio for lead has declined because higher grade deposits were phased into operation in the late 1960's. Bauxite and titanium have had a relatively constant ratio, as have most nonmetal commodities; for many nonmetals the ratio is essentially 1 to 1. The barite ratio has declined in recent years because new mines in Alaska and Nevada have come into production, and the use of this higher grade ore has lowered the ratio.

Exploration and Development.—The downward trend in exploration and development continued in 1972 when 25 million feet, 91% of that in 1971, was reported. Exploration and development statistical data since 1965 have been dominated by activity at uranium mines. Total reported footage for uranium rose from nearly 3 million feet in 1965 to nearly 24 million feet in 1969. During the past 3 years, reported footage has steadily declined, reaching 13 million feet in 1972.

Total footage for metals dropped 2.3 million feet, while nonmetallic footage dropped 303,000 feet. Changes in exploration and development footage for both metals and nonmetals commodities were mixed, with significant increases reported for copper, gold, asbestos, and fluorspar, and significant decreases for silver, lead, uranium, gypsum, and phosphate rock.

Three methods of drilling, diamond, rotary, and percussion, accounted for 94% of the reported footage. Metal mines accounted for 98% of the total footage. However, clay, sand and gravel, and stone operations were not canvassed.

Six States reported over 1 million feet of exploration work. South Dakota led with 20% of the total, followed by New Mexico, 19%; Wyoming, 19%; and Utah, 10%. Exploration and development activity in South Dakota was primarily for gold and uranium, in New Mexico for uranium and copper, in Wyoming for uranium, and in Utah for copper and uranium. Rotary drilling accounted for 53% of all activity. Only percussion drilling indicated an increase in activity as all other methods decreased compared with that of 1971.

Total material handled (ore and waste) from exploration and development activity rose to a record high in 1972. Increased material handled from stripping work at copper, iron ore, and uranium mines more than offset a decrease in tonnage handled at nonmetal mines. Underground tonnage from work such as shaft sinking, raising, and drifting and crosscutting was down sharply at metal mines. Increased activity at underground fluorspar mines accounted for increased material handled from drifting and crosscutting at nonmetal mines.

Three States produced over 100 million tons of material from exploration and development work; two more than in 1971. Arizona led as a result of stripping work in copper, followed by Florida and Wyoming.

Explosives.—The total consumption of explosives in all industries continued to grow and set new yearly record highs. The mining industry accounted for 80% of industrial explosives consumed in 1972, compared with 76.3% in 1968. Total industrial explosives consumption increased by 4.5% compared with that of 1971.

The use of pellet and granular black blasting powder for industrial purposes ceased during 1971. Black blasting powder consumption in the minerals industry reached a record high of 245 million pounds in 1917, mainly in the coal industry. As new explosives were developed, the use of black blasting powder in the minerals industry gradually declined, reaching less than 1 million pounds per year in 1955.

Permissible explosives, primarily used in coal mining, also has shown decreased usage in the minerals industry since reaching a record high consumption of 126 million pounds in 1948. (The use of other mining methods such as strip mining, auger mining, and continuous mining machines in coal accounted for the decline in usage. From 1965 through 1967, interest in using permissible explosives in quarrying and nonmetal mining surged as consumption trebled; however, interest waned and consumption in 1971 and 1972 returned to the levels of that of 1964.

Of the 2.1 billion pounds of explosives consumed in the minerals industry, coal mining accounted for 57%, metal mining 20%, and quarrying and nonmetal mining 23%.

The five top ranked States in order of total explosives and blasting agents consumed were as follows: Kentucky, Pennsylvania, West Virginia, Indiana, and Arizona. In 1972 eight States consumed over 100 million pounds of explosives. Leading States in the use of explosives and blasting agents for coal mining were Kentucky and Indiana; for metal mining, Arizona and Minnesota; and for quarrying and nonmetal mining; Pennsylvania and Illinois.

Beginning in 1972, the Institute of Makers of Explosives (IME) adopted new product classifications for industrial explosives and blasting agents. All of the changes occurred in blasting agents and black blasting powder was deleted as a category. As a result of the change in classification, detailed statistics are not directly comparable with previous years.

More detailed explosive information is published in the Annual Explosive issue of Mineral Industry Surveys prepared by the Division of Nonmetallic Minerals, Mineral Supply, Bureau of Mines.

Statistical Summary

By Staff, Office of Technical Data Services—Mineral Supply

This chapter is a summarization of mineral production data for the United States, its island possessions, the Canal Zone, and the Commonwealth of Puerto Rico. Also included are tables that show the principal mineral commodities exported from and imported into the United States, and that compare world and U.S. mineral production. More detailed data are contained in the commodity chapters of volume I and in the State chapters of volume II of this edition of the Minerals Yearbook.

Mineral production may be measured at any of several stages of extraction and processing. The stage of measurement used in this chapter is what is normally termed "mine output." It usually refers to minerals or ores in the form in which they are first extracted from the ground, but customarily includes the product of auxiliary processing at or near the mines.

Because of inadequacies in the statistics available, some series deviate from the foregoing definition. In the case of gold, silver, copper, lead, zinc, and tin, the quantities are recorded on a mine basis (as the recoverable content of ore sold or treated). However, the values assigned to these quantities are based on the average selling price of refined metal, not the mine value. Mercury is measured as recovered metal and valued at the average New York price for the metal.

The weight or volume units shown are those customarily used in the particular industries producing the commodities. Values shown are in current dollars, with no adjustment made to compensate for changes in the purchasing power of the dollar.

Table 1.—Value of mineral production [1] in the United States, by mineral group

(Millions)

Year	Mineral fuels	Nonmetals (except fuels)	Metals	Total [2]
1968	$16,820	$5,449	$2,698	$24,966
1969	17,965	5,624	3,333	26,921
1970	20,152	[r] 5,712	3,928	[r] 29,792
1971 [r]	21,247	6,058	3,403	30,708
1972	22,084	6,492	3,641	32,217

[r] Revised.

[1] Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

[2] Data may not add to totals shown because of independent rounding.

---

[e] Estimate. [r] Revised. NA Not available.

W Withheld to avoid disclosing individual company confidential data; included with "Value of items that cannot be disclosed." XX Not applicable.

[1] Production as measured by mine shipments, sales, or marketable production (including consumption by producers).

[2] Includes a small quantity of anthracite mined in States other than Pennsylvania. In 1971, value excluded that of Arizona, which is withheld to avoid disclosing individual company confidential data; value included with "Nonmetal items that cannot be disclosed."

[3] Grindstones, pulpstones, grinding pebbles, sharpening stones, and tube mill liners.

[4] Excludes abrasive stone, bituminous limestone, bituminous sandstone, and soapstone, all included elsewhere in table.

Table 3.—Minerals produced in the United States and principal producing States in 1972

Mineral	Principal producing States, in order of quantity	Other producing States
Antimony ore and concentrate	Idaho, Mont., Nev.	
Aplite	Va.	
Asbestos	Calif., Vt., Ariz., N.C.

Tungsten concentrate	Calif., Colo., Nev., Mont	Ariz., Idaho, Oreg., Utah, Wash.
Uranium	N. Mex., Wyo., Tex., Colo	Alaska, S. Dak., Utah, Wash.
Vanadium	Ark., Colo., Idaho, Utah	N. Mex., S. Dak.
Vermiculite	Mont., S.C.	
Wollastonite	N.Y.	
Zinc (mine)	Tenn., Colo., Mo., N.Y	Ariz., Calif., Idaho, Ill., Ky., Maine, Mont., N.J., N. Mex., Okla., Pa., Utah, Va., Wash., Wis.
Zircon concentrate	Fla., Ga.	

Table 4.—Value of mineral production in the United States and principal minerals produced in 1972

State	Value (thousands)	Rank	Percent of U.S. total	Principal minerals, in order of value
Alabama	$371,241	21	1.15	Coal, cement, stone, petroleum.
Alaska	286,138	25	.89	Petroleum, natural gas, sand and gravel, coal.
Arizona	1,091,004	8	3.39	Copper, molybdenum, sand and gravel, cement.
Arkansas	241,179	29	.75	Petroleum, bromine, natural gas, stone.
California	1,851,365	3	5.75	Petroleum, cement, natural gas, sand and gravel.
Colorado	425,841	19	1.32	Petroleum, molybdenum, coal, sand and gravel.
Connecticut	33,123	45	.10	Stone, sand and gravel, feldspar, lime.
Delaware	2,871	50	.01	Sand and gravel, magnesium compounds, clays.
Florida	424,287	20	1.32	Phosphate rock, stone, cement, petroleum.
Georgia	258,041	28	.80	Clays, stone, cement, sand and gravel.
Hawaii	28,074	46	.09	Stone, cement, sand and gravel, pumice.
Idaho	106,206	36	.33	Silver, lead, phosphate rock, zinc.
Illinois	769,787	10	2.39	Coal, petroleum, stone, sand and gravel.
Indiana	322,608	22	1.00	Coal, cement, stone, sand and gravel.
Iowa	134,496	31	.42	Cement, stone, sand and gravel, gypsum.
Kansas	584,537	15	1.81	Petroleum, natural gas, natural gas liquids, cement.
Kentucky	976,910	9	3.03	Coal, stone, petroleum, natural gas.
Louisiana	5,411,543	2	16.80	Petroleum, natural gas, natural gas liquids, sulfur.
Maine	22,922	47	.07	Cement, sand and gravel, stone, zinc.
Maryland	115,501	33	.36	Stone, cement, sand and gravel, coal.
Massachusetts	52,428	43	.16	Sand and gravel, stone, lime, clays.
Michigan	694,767	13	2.16	Iron ore, cement, copper, sand and gravel.
Minnesota	659,669	14	2.05	Iron ore, sand and gravel, stone, cement.
Mississippi	260,681	27	.81	Petroleum, natural gas, sand and gravel, cement.
Missouri	451,817	18	1.40	Lead, cement, stone, iron ore.
Montana	307,676	24	.96	Copper, petroleum, sand and gravel, coal.
Nebraska	73,675	41	.23	Petroleum, cement, sand and gravel, stone.
Nevada	181,702	30	.56	Copper, gold, sand and gravel, diatomite.
New Hampshire	10,111	48	.03	Sand and gravel, stone, clays, gem stones.
New Jersey	113,760	34	.35	Stone, sand and gravel, zinc, magnesium compounds.
New Mexico	1,097,292	7	3.41	Petroleum, natural gas, copper, potassium salts.
New York	320,453	23	.99	Cement, stone, salt, sand and gravel.
North Carolina	116,323	32	.36	Stone, sand and gravel, cement, phosphate rock.
North Dakota	98,086	37	.30	Petroleum, coal, sand and gravel, natural gas.
Ohio	724,748	12	2.25	Coal, stone, lime, cement.
Oklahoma	1,210,728	6	3.76	Petroleum, natural gas, natural gas liquids, cement.
Oregon	76,516	40	.24	Sand and gravel, stone, cement, nickel.
Pennsylvania	1,231,485	5	3.82	Coal, cement, stone, sand and gravel.
Rhode Island	4,291	49	.01	Sand and gravel, stone, gem stones.
South Carolina	82,313	39	.26	Cement, stone, sand and gravel, clays.
South Dakota	65,200	42	.20	Gold, sand and gravel, stone, cement.
Tennessee	269,814	26	.84	Coal, stone, cement, zinc.
Texas	7,211,551	1	22.38	Petroleum, natural gas, natural gas liquids, cement.
Utah	542,809	16	1.68	Copper, petroleum, coal, gold.
Vermont	34,868	44	.11	Stone, sand and gravel, asbestos, talc.
Virginia	489,791	17	1.52	Coal, stone, cement, sand and gravel.
Washington	109,806	35	.34	Cement, sand and gravel, stone, coal.
West Virginia	1,430,632	4	4.44	Coal, natural gas, stone, cement.
Wisconsin	89,353	38	.28	Sand and gravel, stone, iron ore, cement.
Wyoming	746,743	11	2.32	Petroleum, sodium carbonate, natural gas, uranium.
Total	32,217,000	--	100.00

Cobalt...thousand pounds	1,212	2,108	2,597	5,005
Columbium metals, alloys and other forms...do	21	588	29	453
Copper:				
Ore, concentrate, composition metal and unrefined (copper content)...short tons	36,824	30,672	35,562	26,548
Refined copper and semimanufactures...do	215,705	267,303	215,591	278,059
Other copper manufactures...do	7,746	9,145	6,299	7,400
Copper sulfate or blue vitriol...do	2,815	2,078	2,646	1,767
Copper base alloys...do	[r]97,975	[r]106,840	90,377	105,586
Ferroalloys:				
Ferrosilicon...do	25,506	5,603	7,367	2,196
Ferrophosphorous...do	35,111	1,419	1,179	111
Gold:				
Ore and base bullion...troy ounces	577,502	23,470	265,783	14,531
Bullion, refined...do	761,302	27,779	1,206,386	48,522
Iron ore...thousand long tons	3,061	38,147	2,095	26,776
Iron and steel:				
Pig iron...short tons	34,164	2,352	15,018	931
Iron and steel products (major):				
Semimanufactures...do	[r]2,505,864	[r]405,533	2,309,583	400,820
Manufactured steel mill products...do	[r]1,020,206	538,994	1,236,897	605,600
Iron and steel scrap: Ferrous scrap, including rerolling materials...thousand short tons	6,653	222,222	7,683	252,617
Lead:				
Pigs, bars, anodes...short tons	5,925	3,889	8,376	4,500
Scrap...do	[r]17,091	[r]2,268	35,233	4,264
Magnesium: Metal and alloys and semimanufactured forms, n.e.c...do	24,311	15,692	17,556	11,702
Manganese:				
Ore and concentrate...do	55,413	2,683	25,108	3,137
Ferromanganese...do	4,526	1,205	6,842	1,512
Mercury:				
Exports...76-pound flasks	7,232	2,789	400	129
Reexports...do	--	--	563	121
Molybdenum:				
Ore and concentrates (molybdenum content) thousand pounds	46,284	79,111	45,362	73,039
Metals and alloys, crude and scrap...do	222	227	89	199
Wire...do	140	1,212	173	1,551
Semifabricated forms, n.e.c...do	623	1,195	181	987
Powder...do	41	170	50	192
Ferromolybdenum...do	1,355	1,978	509	1,163
Nickel:				
Alloys and scrap (including Monel metal), ingots, bars, sheets, etc...short tons	18,923	48,503	16,694	42,677
Catalysts...do	3,740	10,018	2,573	6,794
Nickel-chrome electric resistance wire...do	643	3,269	553	2,638
Semifabricated forms, n.e.c...do	2,837	12,780	1,851	11,659
Platinum:				
Ore, concentrate, metal and alloys in ingots, bars, sheets, anodes, and other forms, including scrap...troy ounces	320,842	29,432	417,037	44,256
Palladium, rhodium, iridium, osmiridium, ruthenium, and osmium (metal and alloys including scrap)...do	83,768	4,021	121,949	7,511
Platinum-group manufactures, except jewelry	NA	4,769	NA	4,255

Table 9.—U.S. exports of principal minerals and products—Continued

Mineral	1971 Quantity	1971 Value (thousands)	1972 Quantity	1972 Value (thousands)
Metals—Continued				
Rare-earth elements:				
Cerium ore, metal, alloys and lighter flints pounds	60,044	$164	202,206	$610
Silver:				
Ore, concentrates, waste and sweepings thousand troy ounces	3,728	6,164	2,964	4,899
Bullion, refined do	8,496	13,634	26,693	44,361
Tantalum:				
Ore, metal, and other forms thousand pounds	242	2,611	162	2,308
Powder do	85	2,519	171	3,572
Tin:				
Ingots, pigs, bars, etc.:				
Exports long tons	1,821	6,648	857	2,915
Reexports do	441	1,620	277	1,055
Tin scrap and other tin-bearing material except tinplate scrap do	2,605	1,780	8,548	3,392
Titanium:				
Ore and concentrate short tons	1,760	299	1,802	394
Sponge (including iodide titanium and scrap) do	1,711	1,139	3,510	2,165
Intermediate mill shapes and mill products, n.e.c do	430	4,788	562	6,265
Dioxide and pigments do	26,759	9,378	10,334	4,882
Tungsten: Ore and concentrates:				
Exports thousand pounds	2,006	7,323	95	211
Reexports do	1	1	--	--
Vanadium ore and concentrate, pentoxide, etc. (vanadium content) do	520	1,834	351	756
Zinc:				
Slabs, pigs, or blocks short tons	13,346	2,337	4,324	714
Sheets, plates, strips, or other forms, n.e.c do	1,686	1,486	2,419	2,138
Scrap (zinc content) do	2,000	504	1,446	431
Semifabricated forms, n.e.c do	6,042	2,709	6,052	3,076
Zirconium:				
Ore and concentrate do	9,429	802	17,360	940
Metals and alloys and other forms pounds	1,125,242	13,054	1,314,219	11,509
Nonmetals:				
Abrasives:				
Dust and powder of precious or semiprecious stones, including diamond dust and powder thousand carats	7,506	18,726	8,263	21,986
Crushing bort do	20	94	55	305
Industrial diamond do	415	1,831	484	1,889
Diamond grinding wheels do	526	2,932	554	3,073
Other natural and artificial, metallic abrasives and products	NA	37,102	NA	36,956
Asbestos, unmanufactured:				
Exports short tons	52,202	7,571	51,792	7,621
Reexports do	1,476	292	6,832	1,430
Boron: Boric acid, borates, crude and refined do	202,496	24,411	189,778	22,530
Cement do	^{r}109,566	^{r}3,463	100,889	3,712
Clays:				
Kaolin or china clay do	673,083	26,125	667,519	26,332
Fire clay do	161,934	3,566	124,307	2,905
Other clays do	1,137,723	35,638	1,053,892	36,979
Fluorspar do	12,491	525	2,764	184
Graphite do	5,733	680	7,289	888
Gypsum:				
Crude, crushed or calcined thousand short tons	^{r}49	2,318	51	2,582
Manufactures, n.e.c	NA	1,896	NA	2,694
Kyanite and allied minerals short tons	31,554	2,097	73,911	3,737
Lime do	65,862	1,971	37,659	1,242
Mica sheet, waste and scrap and ground pounds	14,383,388	1,209	13,957,313	1,842
Mica, manufactured do	798,956	2,559	1,001,639	2,910
Mineral-earth pigments: Iron oxide, natural and manufactured short tons	^{r}10,545	^{r}5,812	8,194	5,087
Nitrogen compounds (major) thousand short tons	3,126	141,381	4,004	222,441
Phosphate rock do	12,687	94,816	13,992	107,438

Table 10.—U.S. imports for consumption of principal minerals and products—Continued

Mineral	1971 Quantity	1971 Value (thousands)	1972 Quantity	1972 Value (thousands)
Metals—Continued				
Minor metals: Selenium and salts pounds	409,264	$4,134	448,964	$4,362
Nickel:				
Pigs, ingots, shot, cathodes short tons	100,531	259,931	125,364	300,825
Scrap do	1,336	1,896	2,306	3,517
Oxide do	5,769	11,604	5,988	12,038
Platinum group:				
Unwrought:				
Grains and nuggets (platinum) troy ounces	34,958	3,170	58,284	7,254
Sponge (platinum) do	[r] 329,967	[r] 36,882	350,143	42,622
Sweepings, waste and scrap do	75,031	7,477	75,210	7,600
Iridium do	14,293	1,908	24,827	4,038
Palladium do	[r] 220,883	[r] 7,919	289,055	12,929
Rhodium do	33,764	5,980	47,378	8,735
Ruthenium do	28,063	1,222	61,191	2,602
Other platinum-group metals do	15,037	2,067	103,734	12,148
Semimanufactured:				
Platinum do	105,806	11,475	207,960	22,869
Palladium do	442,465	15,198	613,174	22,488
Rhodium do	898	169	3,426	543
Other platinum-group metals do	1,575	207	6,920	473
Radium: Radioactive substitutes	NA	5,671	NA	4,444
Rare-earth elements: Ferrocerium and other cerium alloys pounds	16,190	82	27,867	94
Silver:				
Ore and base bullion thousand troy ounces	33,452	45,003	33,768	49,979
Bullion do	22,388	33,979	25,680	41,579
Tantalum ore thousand pounds	1,180	3,332	1,229	2,663
Tin:				
Ore (tin content) long tons	3,060	10,564	4,216	12,475
Blocks, pigs, grains, etc do	46,940	164,403	52,451	195,421
Dross, skimmings, scrap, residues and tin alloys, n.s.p.f do	4,125	1,385	1,304	2,140
Tin foil, powder, flitters, etc	NA	[r] 4,472	NA	6,501
Titanium:				
Ilmenite [1] short tons	378,049	10,459	395,218	14,287
Rutile do	215,109	23,155	195,068	21,733
Metal pounds	6,594,448	6,355	8,769,356	8,041
Ferrotitanium do	173,057	154	181,326	76
Compounds and mixtures do	86,230,153	16,125	173,597,069	33,908
Tungsten: (tungsten content)				
Ore and concentrates thousand pounds	418	1,033	5,739	12,189
Metal do	17	117	61	342
Other alloys do	129	1,804	644	2,902
Zinc:				
Ore (zinc content) short tons	467,368	62,678	174,063	24,275
Blocks, pigs, and slabs do	[r] 324,255	[r] 93,628	516,643	176,707
Sheets do	509	237	485	310
Old, dross, and skimmings do	1,967	287	2,882	2,170
Dust do	8,184	2,949	9,197	3,822
Manufactures	NA	1,347	NA	2,040
Zirconium: Ore, including zirconium sand do	96,387	3,656	67,537	3,291
Nonmetals:				
Abrasives: Diamond (industrial) thousand carats	12,910	46,023	15,134	52,619
Asbestos short tons	681,367	80,090	735,515	87,732
Barite:				
Crude and ground do	484,762	4,490	624,634	5,658
Witherite do	511	42	1,311	169
Chemicals do	7,800	1,299	23,592	3,959
Cement do	[r] 3,088	44,348	4,894	71,530
Clays:				
Raw do	58,965	1,289	62,576	1,095
Manufactured do	5,084	212	4,138	214
Cryolite do	23,127	5,056	25,642	3,451

See footnotes at end of table.

Table 10.—U.S. imports for consumption of principal minerals and products—Continued

Mineral	1971		1972	
	Quantity	Value (thousands)	Quantity	Value (thousands)
Nonmetals—Continued				
Feldspar: Crude....long tons	120	$19	167	$23
Fluorspar....short tons	1,072,405	34,530	1,181,533	47,851
Gem stones:				
Diamond....thousand carats	4,667	463,242	5,506	626,679
Emeralds....do	351	7,731	573	22,176
Other	NA	55,010	NA	67,281
Graphite....short tons	[r] 57,756	2,727	64,135	3,847
Gypsum:				
Crude, ground, calcined thousand short tons	6,096	13,552	7,720	18,494
Manufactures	NA	2,780	NA	3,548
Iodine, crude....thousand pounds	7,275	11,510	6,207	10,184
Kyanite....short tons	1,343	65	124	6
Lime:				
Hydrated....do	39,807	618	37,468	724
Other....do	202,477	2,690	210,995	3,224
Magnesium compounds:				
Crude magnesite....short tons	7	(2)	--	--
Lump, ground, caustic calcined magnesia....do	11,518	736	10,376	675
Refractory magnesia, dead-burned fused magnesite, dead-burned dolomite....do	129,025	10,014	133,734	9,695
Compounds....do	49,731	1,257	25,301	1,111
Mica:				
Uncut sheet and punch thousand pounds	1,355	1,171	1,494	1,162
Scrap....do	7,284	171	2,641	62
Manufactures....do	4,464	2,476	5,644	3,183
Mineral-earth pigments: Iron oxide pigments:				
Natural....short tons	1,794	171	2,777	236
Synthetic....do	28,236	5,592	34,274	7,602
Ocher, crude and refined....do	--	--	98	6
Siennas, crude and refined....do	1,427	125	1,272	196
Umber, crude and refined....do	4,681	228	8,234	412
Vandyke brown....do	358	39	621	77
Nitrogen compounds (major), including urea....thousand short tons	2,573	118,281	2,683	125,037
Phosphate, crude....do	84	2,478	57	1,544
Phosphatic fertilizers....do	92	6,972	70	3,184
Pigments and salts:				
Lead pigments and compounds short tons	[r] 27,893	[r] 7,647	26,550	9,244
Zinc pigments and compounds do	[r] 20,913	4,187	25,934	6,891
Potash....do	4,687,379	118,481	4,996,415	128,548
Pumice:				
Crude or unmanufactured....do	8,833	109	9,094	149
Wholly or partly manufactured do	390,900	975	589,758	1,351
Manufactures, n.s.p.f	NA	18	NA	24
Quartz crystal (Brazillian pebble) pounds	752,001	368	462,740	331
Salt....thousand short tons	3,855	14,429	3,463	11,979
Sand and gravel:				
Glass sand....do	48	243	49	201
Other sand and gravel....do	667	984	712	1,178
Sodium sulfate....do	[r] 268	4,667	299	5,358
Stone and whiting	NA	33,643	NA	43,472
Strontium: Mineral....short tons	45,505	1,115	30,677	830
Sulfur and pyrites:				
Sulfur ore and other forms n.e.s. thousand long tons	[r] 1,299	25,419	1,138	16,288
Pyrites....do	285	962	125	472
Talc: Unmanufactured....short tons	17,382	745	29,085	1,669
Fuels:				
Carbon black:				
Acetylene....pounds	6,125,541	1,405	6,022,118	1,581
Gas black and carbon black....do	386,246	41	1,149,099	176
Coal:				
Bituminous, slack, culm and lignite short tons	111,036	1,772	47,098	691

See footnotes at end of table.

[p] Preliminary. [r] Revised. NA Not available. W Withheld to avoid disclosing individual company confidential data.

[1] Total is not strictly comparable with previous years because it does not represent total world production. Confidential U.S. data are excluded. These data include reported figures and reasonable estimates. In some instances where data were not available, no reasonable estimate could be made and none has been included except for gold, silver and pyrites.

[2] Includes small quantities of lignite for People's Republic of China, and Pakistan, and anthracite for Colombia.

[3] Includes low- and medium-temperature and gashouse coke.

[4] Includes Puerto Rico.

[5] Kaolin sold or used by producers.

[6] Year ended June 30 of year stated (United Nations).

[7] World total exclusive of the U.S.S.R.

[8] Dry bauxite equivalent of crude ore.

[9] Includes secondary.

[10] Recoverable.

[11] Includes byproduct ore.

[12] Less than ½ unit.

[13] Smelter output from domestic and foreign ores, exclusive of scrap. Production from domestic ores only, exclusive of scrap, was as follows: 1970—1,605,265; 1971—1,470,815; 1972—1,649,130.

[14] Lead refined from domestic and foreign ores, excludes lead refined from imported base bullion.

[15] Data from American Iron and Steel Institute. Excludes production of castings by companies that do not produce steel ingots.

[16] Includes tin content of alloys made directly from ores.

Abrasive Materials

By Robert G. Clarke [1]

The output of natural abrasives increased 15% in quantity compared to that of 1971, and the value increased 12%, excluding the value of emery. Production of tripoli types increased 17% in quantity and 40% in value. Output of silica stone products increased 38% in quantity and 19% in value. The production of garnet was essentially unchanged in quantity but increased 1% in value. The production of emery increased 82% in quantity.

The production of artificial abrasives increased in both quantity and value for all types. Production of aluminum oxide increased 23% in quantity and 17% in value. Production of silicon carbide increased 28% in quantity and 17% in value. Production of metallic abrasives increased 22% in quantity and 19% in value. The overall increases for artificial abrasives were 24% in quantity and 18% in value.

Industrial diamond imports increased 14% in value. Exports plus reexports of industrial diamond increased 18% in caratage and 20% in value.

FOREIGN TRADE

Imports of abrasive materials reversed the decline that started in 1968 and were 20% more in value than in 1971. Exports plus reexports also increased. Net imports, the excess of imports over exports and reexports, were $15.5 million, a 132% increase over 1971 net imports. The domestic manufacture of synthetic diamond and export trade in other industrial diamond had an important influence on the value of exports.

Table 1.—Salient abrasive statistics in the United States

[2] Quantity not reported.

TRIPOLI

Although they differ in some respects, fine-grained, porous, silica materials are discussed as a group because they have similar properties and end uses. They include tripoli from Arkansas, Missouri, and Oklahoma; amorphous or soft silica from Illinois; and rottenstone from Pennsylvania. Production of crude tripoli (table 1) increased 17% in quantity and 40% in value. Finished material (table 5) for abrasive use was 63% of the total and material for filler use was 35%, compared with 67% and 31%, respectively, in 1971.

Tripoli producers in 1972 were Malvern Minerals Co., Garland County, Ark., and The Carborundum Co., Newton County, Mo., and Ottawa County, Okla. The major use for tripoli was for abrasive applications; it was also used as a filler. Amorphous silica producers were Illinois Min-

Table 5.—Processed tripoli [1] sold or used by producers in the United States, by use [2]

Use	1967	1968	1969	1970	1971	1972

[1] Includes amorphous silica and Pennsylvania rottenstone.

[2] Partly estimated.

[3] Data may not add to totals shown because of independent rounding.

erals Co. and Tammsco, Inc., both in Alexander County, Ill. Rottenstone producers were Keystone Filler & Manufacturing Co. and Penn Paint & Filler Co., both in Lycoming County, Pa. Amorphous silica and rottenstone were also used for abrasives and fillers.

Hercules Minerals Corp., Pike County, Ark., a former tripoli producer, ceased operations in June. Penn Paint & Filler Co., Lycoming County, Pa. operated until June when Hurricane Agnes so badly damaged all installations that the company ceased operations.

Prices quoted in Engineering and Mining Journal, December 1972, for tripoli and amorphous silica were as follows:

Tripoli, paper bags, carload lots, f.o.b., cents per pound:

White, Elco, Ill.: Air floated through 200 mesh	1.30
Rose and cream, Seneca, Mo., and Rogers, Ark.:	
Once ground	2.90
Double ground	2.90
Air float	3.15
Amorphous silica, bags, f.o.b., dollars per ton:	
Illinois:	
Through 200 mesh, 90 to 95 percent	26
Through 200 mesh, 96 to 99 percent	27
Through 325 mesh, 90 to 95 percent	29
Through 325 mesh, 96 to 98 percent	30.50
Through 325 mesh, 98 to 99.4 percent	31.50
Through 325 mesh, 99.5 percent	45
Through 400 mesh, 99.9 percent	65
Below 15 microns, 99 percent	72
Below 10 microns, 99 percent	92
Dierks, Ark.:	
200 mesh	28
325 mesh	33

SPECIAL SILICA STONE PRODUCTS

Special silica stone products included the following: oilstones from Arkansas, whetstones from Indiana, grindstones from Ohio, grinding pebbles and deburring media from Minnesota and Wisconsin, and tube-mill liners from Minnesota. Production increased 38% in quantity and 19% in value.

Novaculite for oilstones was produced by Arkansas Abrasives, Inc., Arkansas Oilstones Co., Inc., John O. Glassford, Cleve Milroy, M. V. Smith, Hiram A. Smith Whetstone Co., and Norton Pike Division of Norton Co., all from operations in Garland County, Ark. Hindostan Whetstone Co. produced whetstone in Orleans County, Ind. Cleveland Quarries Co. produced grindstones at its Amherst quarry, Amherst County, Ohio. Jasper Stone Co. produced both grinding pebbles and tube-mill liners from its quarry in Jasper County, Minn. Baraboo Quartzite Co., Inc., produced deburring media at its quarry in Sauk County, Wis.

Table 6.—Special silica-stone products sold or used in the United States [1]

Year	Quantity (short tons)	Value (thousands)
1968	3,141	$629
1969	3,311	600
1970	3,184	665
1971	2,349	563
1972	3,241	670

[1] Includes grinding pebbles, grindstones, oilstones, tube-mill liners, and whetstones.

NATURAL SILICATE ABRASIVES

Garnet.—Sales of domestic garnet were slightly less in quantity and slightly more in value. Producers finished their products by crushing, grinding, and screening to specified particle sizes and grits. There were four active producers—two in New York and two in Idaho. Barton Mines Corp., Warren County, N.Y., the largest producer, processed the garnet for use in coated abrasives, glass grinding and polishing, and metal lapping. Also in New York, Interpace Corp., Essex County, recovered garnet as a byproduct in the processing of wollastonite ore. Idaho Garnet Abrasive Co. and Emerald Creek Garnet Milling Co. produced

Table 7.—Abrasive garnet sold or used by producers in the United States

Year	Quantity (short tons)	Value (thousands)
1968	22,136	$1,922
1969	20,458	1,874
1970	18,837	1,936
1971	18,984	1,934
1972	18,916	1,957

garnet from placer deposits in Benewah County, Idaho. The latter three producers reported use of garnet for various purposes: sandblasting, water filtration, nonskid paints, and miscellaneous abrasive applications.

Prices for New York garnet, f.o.b. North Creek, N.Y., 2,000-pound release, in 330- to 370-pound containers, cents per pound, were as follows:

Untreated for manufacturing of coated abrasives:	
Grades 16 through 36	18
Grades 40 through 220	20
Grades 240 through 280	25
Grades 320 through 600	22
Untreated for technical grinding and lapping:	
Mesh sizes 20 to 240	17
Mesh sizes 280 to 360	23
Micron sizes 27 to 23	26
Micron sizes 20 to 8	30
Micron sizes 6 to 5	22
Micron sizes 4 to 2	39

Prices for Idaho garnet, f.o.b. Seattle, group sizes, were 5.5 to 9 cents per pound.

NATURAL ALUMINA ABRASIVES

Corundum.—Commercial production of abrasive-grade corundum was last reported in the United States in 1918. In recent years, except in 1971, all of the corundum used by domestic industry was imported from Southern Rhodesia, but this trade was halted by the imposition of sanctions in 1968 by the United Nations. A small quantity of crude corundum was imported from Kenya in 1971. Also in 1971, Bendix Abrasives Division, Westfield Facility, of Westfield, Mass., acquired 1,964 short tons of corundum in Government stockpiles after Congressional approval was granted. The Office of Emergency Preparedness in 1969 had dropped corundum from the list of strategic and critical materials for stockpiling.

Corundum was crushed and classified to obtain a commercial product in a number of specified particle size ranges. Its use was chiefly for the grinding and finishing of optical lenses.

Table 8.—Natural corundum: World production, by country

(Short tons)

Country [1]	1970	1971	1972 [p]
India	454	345	422
Kenya	66	[e] 70	[e] 70
Malagasy Republic	2	[r] 1	[e] 1
Malawi	(2)	(2)	NA
South Africa, Republic of	272	[r] 266	324
U.S.S.R.[e]	7,200	7,200	7,700
Total	7,994	[r] 7,882	8,517

[e] Estimate. [p] Preliminary. [r] Revised. NA Not Available.

[1] In addition to the countries listed, Southern Rhodesia may have continued to produce natural corundum at a significant level (several thousand tons annually), but available information is inadequate to make reliable estimates of output levels.

[2] Less than ½ unit.

Emery.—Domestic production of emery in 1972 was by two producers, De Luca Emery Mine, Inc., near Peekskill in Westchester County, N.Y., and Oregon Emery Co., near Sweethome in Linn County, Oreg. Data on value of production were withheld to avoid disclosing individual company confidential data. The quantity of production, 2,883 tons, was nearly double that of 1971. Emery use was mostly in aggregate for heavy-duty nonslip floors, pavements, and stair treads. A minor use was in coated abrasives and tumbling abrasives.

INDUSTRIAL DIAMOND

Domestic production of synthetic industrial diamond in 1972 was estimated to be 15 million carats, up 2 million carats from 1971. Secondary production comprising salvage from used diamond tools and from wet and dry diamond-containing wastes was estimated to be 3 million carats.

The Government stockpile inventory as of December 31, 1972, was up to the objectives of 23.7 million carats of crushing bort and 20.0 million carats of stones. The objective for small diamond dies was 25,000. Congressional approval was granted in August 1971 for the disposal of excesses. As of December 31, 1972, excesses amounted to 18.1 million carats of bort and 3.4 million carats of stones; 473 small diamond dies were excess.

Exports and reexports of industrial diamond dust and powder, which included synthetics, were 8.6 million carats valued at $22.8 million. Crushing bort, except dust and powder, exported amounted to 384,000 carats valued at $2.2 million. Exports of stones were 4.3 million carats valued at $25.8 million. The total of exports and reexports of dust and powder, bort, and stones increased from 11.3 million carats in 1971 to 13.3 million carats, and the value increased from $42.2 million to $50.8 million.

Imports of industrial diamond in 1972 increased 17% in number of carats and 14% in value from 1971. Shipments from Ireland were 7.5 million carats valued at $17.9 million, increases of 25% in quantity and 13% in value respectively in 1972 over the 1971 figures. The share of imports from Ireland was 49% of quantity and 34% of value.

Table 9.—U.S. imports for consumption of industrial diamond (excluding diamond dies)

(Thousand carats and thousand dollars)

Year	Quantity	Value
1970	13,365	49,037
1971	12,910	46,023
1972	15,134	52,619

WORLD REVIEW

Angola.—Diamond production from Angola's sole producer in 1971, Companhia de Diamantes de Angola (DIAMANG), was 2,413,000 carats. Exports were 2,340,087 carats in 1971 but the total earnings to Angola decreased because gem-quality diamond was less and world prices for gem diamond were depressed.. The average value per carat decreased 30%. In 1971 DIAMANG treated 4.14 million cubic meters of diamond-bearing material at an average grade of 0.58 carat per cubic meter. Plans by DIAMANG for 1972 were expected to yield the same production in carats but at a higher value because of increased world prices.

In 1972, the consortium formed by DIAMANG and De Beers Consolidated Mines Ltd. of Kimberley, Republic of South Africa, known as Consorcio Mineiro de Diamantes, was active in exploration and development. The consortium was allowed to prospect 500,000 square kilometers (km^2) in 1972, but its area will decrease to 30,000 km^2 by 1977. DIAMANG was assigned an area of 50,000 km^2.

Areas assigned to other concessionaires ranged in size from 25,700 km^2 to 5,286 km^2. By size of concession, the concessionaires were Companhia de Diamantes do Oeste de Angola, Companhia Nacional de Diamantes, Companhia Ultramarina de Diamantes, and Companhia Internacional de Exploração de Diamantes.

Australia.—No commercial quantities of diamond have been found in Australia to the present. However, in 1972 a kimberlitic eruption-type crater was located in northern New South Wales. Over A$500,000 was allocated to explore an area of 1,500 to 2,000 acres.[2]

Belgium.—The Antwerp Diamond Co. announced formation of a venture with Almazjuvelirexport of the U.S.S.R. for exclusive world sales rights for all Russian diamonds.

Botswana.—The Orapa diamond mine was officially opened on May 26, 1972, in a ceremony attended by the President of Botswana and the Chairman of the Board of De Beers. The mine actually went onstream in June 1971; the open pit operation processed 8,000 tons per day with an above-average caratage per ton. The value per ton processed is low because industrial diamonds are more than 50% by weight of the yield. The use of sophisticated concentrating equipment, which includes a heavy-media cyclone plant and X-ray separators, was claimed to effect a nearly 100 percent recovery of diamond.[3]

Canada.—The Ontario Department of Mines and Northern Affairs recommended further exploration for diamond based on the demonstrated favorable environment in Northern Ontario.[4]

Central African Republic.—The Government established a National Diamond Agency in March 1972 to organize all dia-

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Total (gem plus industrial) diamond output of each country is actually reported except where indicated to be an estimate by footnote. In contrast, the detailed separate reporting of gem diamond and industrial diamond represent Bureau of Mines estimates in the case of all countries except Lesotho (all years), Liberia (1970 and 1971) and Venezuela (all years) where sources give both total output and detail. The estimated distribution of total output between gem and industrial diamond is conjectural in the case of a number of countries, based on unofficial information of varying reliability.

[2] Official estimate by Government of Guinea.

[3] Exports of diamond originating in Lesotho; excludes stones imported for cutting and subsequently re-exported.

[4] Exports for year ended August 31 of that stated.

[5] Exports

[6] All company output from the Republic of South Africa except for that from the Premier mines; also excludes company output from the Territory of South-West Africa and from Botswana.

mond activities to the benefit of the Central African Republic.

Ghana.—In June 1972, the Government notified foreign mining companies of its intent to obtain a majority control of all mining ventures. The Consolidated African Selection Trust diamond mine at Akwatia was affected by the decree.

India.—All production of diamond in India came from the Panna District of Madhya Pradesh State, under the direct control and supervision of the Government-owned National Mineral Development Corp. The 1972 output was 19,747 carats estimated to be 82% gem diamond and 18% industrial. To sustain the indigenous diamond industry, India imported both gem and industrial diamond.

Lesotho.—The Lesotho Department of Mines and Geology reported the value of diamond exports declined 8% in 1972 from that of 1971.[5] London and Rhodesian Mining and Land Co. ceased prospecting operations at Kao in Butha Buthe district, which it had began in 1969 after spending $1.25 million in prospecting. Rio Tinto-Zinc Corp pulled out of Letseng-La-Terai in the Mokhotlong district after spending $3.75 million on prospecting. Newmont Mining

---

[5] Mineral Trade Notes. V. 70, No. 3, March 1973, pp. 3–4.

Corp. began prospecting at Kao in late 1971, and its expenses to the end of 1972 were $1.9 million.

The Government of Lesotho and the Embassy of the United States in Lesotho announced approval of a request to include Lesotho in an electronic photo survey by a U.S. Earth Resources Technology Satellite to be launched by the U.S. National Aeronautics and Space Administration. The satellite imagery will be supplemented by ground research of favorable areas for diamond deposits by the Lesotho Department of Mines and Geology.

Sierra Leone.—The third largest diamond ever found, "Star of Sierra Leone," 968.9 carats, was removed from the vibrating grease belt in the separator plant of The National Diamond Mining Co., Ltd. (DIMINCO) mine at Yengema on February 14, 1972.[6] DIMINCO operated at full capacity on its lease, which is in an alluvial area similar to that of many concessions operated by thousands of unincorporated diggers. The life of the alluvial diggings was estimated to be 3 to 5 years. Hence, DIMINCO conducted prospecting by drilling in its lease area for kimberlite. Diamond exports accounted for more than 60% of the value of exports from Sierra Leone. If the life of the alluvial diggings is as short as indicated, a vast change in the country's economy will occur.[7]

South Africa, Republic of.—Over 40% of the gem quality diamond output of the world in the last 5 years was credited to South Africa and South West Africa combined.[8] The combined total was 20% of the total world natural diamond production —both gem and industrial. The DeBeers group produced 90% of the area output.

U.S.S.R.—Synthetic diamonds were introduced to industry in the U.S.S.R. about 1962. Currently out of every 100 carats of diamond used in Soviet industry, 85 carats are synthetic.[9] Natural diamond mined in Siberia is equal in production to that of South Africa, according to a representative of V-O Almazjuvelirexport, the U.S.S.R. foreign trade organization at a trade fair in Seattle.[10]

Zaire.—Zaire maintained its position as the world's leading source of industrial diamond. Production was limited because of competition from synthetic diamond.[11]

TECHNOLOGY

A claim was made that the U.S.S.R. state standards were the first in the world for the strength of grains of polishing powders, for abrasive capacity, and for surface roughness of the finished work. These standards, U.S.S.R. GOST 9206–70, applied to synthetic diamond powders.[12] The Industrial Diamond Association of India in cooperation with the De Beers Industrial Diamond Division of the United Kingdom held a seminar, December 4–5, 1972, which included a number of foreign expert speakers. A claim for the U.S.S.R. was that synthetic diamond of ballas and carbonado type have been created. The claim was also made that "slavutich," a superhard material which is a formed or shaped sintered synthetic material, may be substituted for natural diamond stones.

In the United States, it was claimed that sintered polycrystalline diamond can be preshaped to any form. . . . "points, wedges, plates, pierced parts and rollers . . . up to 20 carats."[13] In some applications, cubic boron nitride proved superior to diamond.[14] Scientists at the General Electric Research and Development Center reported the development of cutting tool inserts fabricated from synthetic diamond and cubic boron nitride into polycrystalline compacts backed by cemented tungsten carbide.[15]

An international file of abstracts relative to properties of diamond, hard materials, machines, and patents was published monthly.[16]

ARTIFICIAL ABRASIVES

Crude fused aluminum oxide was produced in 1972 by five firms in the United States and Canada. The Carborundum Co., Norton Co., and General Abrasive Co., Inc., each operated plants in both countries. The Exolon Co. and Simonds Canada Abrasive Co., Ltd., operated plants in Canada. Output of white, high-purity material was 24,485 tons and of regular grade was 159,843 tons. Thirteen percent of the combined output of white and regular was used for nonabrasive applications, principally in the manufacture of refractories. Output was 63% of rated plant capacity.

Silicon carbide was produced in 1972 by six firms in the United States and Canada. The Carborundum Co. operated plants in both countries and Electro-Refractories & Abrasives, Ltd., The Exolon Co., Norton Co., and General Abrasive Co., Inc., operated in Canada; all produced crude for abrasive, refractory, and miscellaneous uses. Satellite Alloy Corp. operated in the United States and produced crude for refractories and other nonabrasive applications. Production was 85% of capacity and consumption was 57% for abrasive use and 43% for refractory and other nonabrasive applications.

The manufacture of metallic abrasives in 1972 increased 17% in quantity and 19% in value. Of the total quantity sold or used, steel shot and grit was 75%; chilled iron shot and grit, 16%; annealed iron shot and grit, 9%. Other metallic abrasives sold or used in small quantities included aluminum, copper, and zinc, and metallic oxides and carbides. Production from Ohio was 30% of the total quantity, the highest of the producing states. Michigan, Pennsylvania, and Indiana followed in rank of quantity and their combined output was 62% of the total. The remaining 8% was produced by Alabama, New York, and Connecticut. Industrial Corp. of Pittsburgh, Pa., recycled metallic abrasives for other producers and consumers.

Producers of metallic abrasives were as follows:

Company	Plants
Abbott Ball Co	Hartford, Conn.
Abrasive Materials, Inc	Hillsdale, Mich.
Abrasive Metals Co	Pittsburgh, Pa.
The Carborundum Co	Butler, Pa.
Cleveland Metal Abrasive Co	Birmingham, Ala. Howell, Mich. Springville, N.Y. Cleveland, Ohio Toledo, Ohio
Durasteel Co	Pittsburgh, Pa.
Ervin Industries	Adrian, Mich.
Globe Steel Abrasive Co	Mansfield, Ohio
Metal Blast, Inc	Cleveland, Ohio
National Metal Abrasive Co	Do.
Pellets, Inc	Tonowanda, N.Y.
Steel Abrasives, Inc	Hamilton, Ohio
Wheelabrator-Frye, Inc	Mishawaka, Ind.

TECHNOLOGY

Silicon carbide was produced from waste rice hulls and iron oxide in a process developed at the University of Utah by Dr. Ivan B. Cutler and associates.[17] The silicon carbide from the process was finely crystalline.

Zirconia alumina abrasive was used in coated abrasives for the first time and was claimed to have greater life and faster cut than any other abrasive.[18]

The number of patents describing abrasive materials used in abrasive and refractory products was large, but most of the

Aluminum

By John W. Stamper [1]

Consumption of aluminum in the United States increased dramatically, and the industry's oversupply problem, which was at its worst in 1970 and 1971, appeared to be ended. Production facilities that had been closed during 1970–71 were reopened, and the operating rate was increased markedly, although output increased at a slower rate than demand.

World demand also increased significantly, and the oversupply of the past few years in most countries was eased somewhat. World output increased 6.4%, compared with an estimated 10% increase in demand. The largest production increase was in Asia, where Japan produced about 14% more than in 1971. The world operating rate was 85% of yearend capacity, compared with an 83% rate during 1971.

Table 1.—Salient aluminum statistics

World: Production	8,839	9,885	10,641	11,375	12,103

Legislation and Government Programs.—During 1972, 6,125 short tons of primary aluminum was sold from Government inventories under the long-range disposal contracts between industry and the General Services Administration that were implemented in December 1965. The total quantity sold under the program from December 1965 through December 1972 was 623,498 short tons.

Contracts between the Government and aluminum producers, covering industry purchases of surplus aluminum metal from U.S. stockpiles, were amended in December to provide for the sale of 120,000 tons of metal per year during the 3-year period beginning July 1, 1972. Annual industry purchases under the amended contracts after July 1, 1975, were scheduled to decline over the years through 1990. The aluminum stockpile objective of 450,000 tons was reduced to zero on December 20, 1972, and the sales could include the entire quantity of aluminum held in Government inventories which totaled about 1,263,000 tons.

The Bureau of Domestic Commerce (BDC), U.S. Department of Commerce, established aluminum set-asides each quarter during 1972 to meet the estimated requirements of the Department of Defense, Atomic Energy Commission, National Aeronautics and Space Administration, and related defense programs. The set-aside for the year was 250,000 short tons, down from 315,000 tons in 1971 and 455,000 tons in 1970.

The Bureau of Customs received information from a domestic firm on April 7, 1972, indicating a possibility that aluminum ingot from Canada was being sold, or was likely to be sold, in the United States at less than fair value within the meaning of the Antidumping Act of 1921, as amended. Having conducted a summary investigation as required and having determined that there were grounds for so doing, the Bureau of Customs instituted an inquiry to verify the information submitted and to obtain the facts necessary to enable the Secretary of the Treasury to reach a determination as to the fact or likelihood of sales at less than fair value. The Bureau of Customs concluded that the information received tended to indicate that the prices of aluminum ingot sold for exportation to the United States from Canada were less than the prices of sales for consumption in Canada. At yearend, the matter was still under study by the Department of the Treasury.

---

[1] Physical scientist, Division of Nonferrous Metals.

DOMESTIC PRODUCTION

Primary.—Some aluminum production facilities that had been shut down during the 1970–71 period of oversupply were reopened in 1972 and primary output increased by 5%.

Annual capacity at the Alcoa, Tenn., plant of the Aluminum Company of America (Alcoa) was increased by 70,000 tons, and capacity at the Hannibal, Ohio, plant of Ormet Corp. was raised 10,000 tons per year. The operating rate of the industry based on the entire year was 86.9% of yearend capacity, compared with an 84.2% rate in 1971. The rate of production in December 1972 was 90.4% of yearend capacity, compared with a rate of 81.9 during December 1971 on the same basis.

Electric energy supply was curtailed in the Pacific Northwest during the latter part of the year, owing to low water conditions, delays in starting up new hydro facilities and a coal-fired steam electric generating plant at Centralia, Wash., and a temporary shutdown, for refueling, of the nuclear powerplant at Hanford, Wash. The Bonneville Power Administration (BPA) announced that it would raise its power rates to the aluminum industry by 25% in December 1974 and probably by another 25% in 1979. Power rates to the aluminum industry in the Pacific Northwest, which is served by BPA, were believed to average about 2.5 mills per kilowatt-hour in 1972.

Alcoa restarted several of its potlines that had been closed during 1970–71 and began modernizing its Massena, N.Y., primary aluminum plant, replacing three potlines that were built during World War II. The company continued to plan construction of a magnesium plant at Addy, Wash., which was scheduled for completion in 1975. Most of the magnesium output of the plant, as well as coproduct silicon metal, was expected to be used by Alcoa in aluminum alloys. In 1972, only Reynolds Metals Co. (Reynolds) had captive silicon production facilities (at Listerhill, Ala.). Other primary producers as well as secondary smelters purchased silicon requirements.

The worlds largest rolling mill, capable of reducing aluminum ingots to finished plate 18 feet wide (4 feet wider than previously available), was officially opened by Alcoa at Davenport, Iowa. Finished aluminum plate up to 8 inches in thickness or tapered aluminum plate of extreme widths reportedly can be produced at the mill. The company established a Technology Marketing Division to coordinate and market its

Table 2.—Production and shipments of primary aluminum in the United States

(Short tons)

proprietary processing, engineering, and aluminum plant construction capabilities. Alcoa planned to expand its aluminum metal powder production operations to include fabrication of powdered products with the purchase of the assets of the Powdered Metal Division of the Barden Corp. at North Haven, Conn.

Alcoa announced that it was developing a new primary aluminum production process that was 30% more efficient than the presently used Hall process (see Technology). The new process was scheduled to be tested on a semicommercial scale in a 15,000-ton-pilot-plant in 1975. The company also purchased, near Laramie, Wyo., a large deposit of anorthosite, one of several alternatives to bauxite as a source of aluminum.

American Metal Climax, Inc. (AMAX), reportedly deferred plans to begin construction of a 75,000-ton-per-year aluminum plant between Guyana and Aguirre on the south coast of Puerto Rico. How-

ever, the company reportedly concluded a long-term agreement with Alcoa for the purchase of 440,000 short tons of alumina per year from Australia. AMAX had been purchasing about 250,000 tons per year from Alcoa for reduction to aluminum metal at the Ferndale, Wash., aluminum plant, operated by Intalco Aluminum Corp. The corporate structure and operations of the aluminum group of AMAX were described in a report.[2]

Construction of The Anaconda Company alumina reduction plant at Sebree, Ky., continued, with initial production from the 120,000-ton-per-year facility scheduled for the second quarter of 1973. The company also announced an agreement, in principle, to purchase the Russell Aluminum Corp., an important fabricator of finished and semifinished aluminum products.[3]

Kaiser Aluminum & Chemical Corp. reactivated potlines at Chalmette, La., and Ravenswood, W. Va. Total capacity of the lines, which had been closed during 1970 and 1971 owing to market conditions, was about 70,000 tons per year. The company indicated that it would accelerate its $15 million pollution control program at Mead, Wash., and asked permission to reopen two lines at that location with a production equivalent of 52,000 tons of aluminum per year.

National-Southwire Aluminum Co., a primary aluminum producer, and Colorado Central Mines, Inc., announced a joint venture to investigate the use of alunite instead of bauxite as a source of aluminum metal. A pilot plant was being constructed near Golden Colo., to test the alunite from a deposit in Utah controlled by the two firms. Olin Corp., a diversified chemical, paper, and metal producer, announced that it planned to dispose of its aluminum operations. The company indicated that the proposed sale included its 50% share of the primary aluminum production and rolling facilities at Hannibal, Ohio, operated by the Ormet Corp., and seven separate fabricating plants (four extrusion operations, two conductor plants, and an architectural products plant) around the country. Olin's 40% equity in Compagnie International pour la Production de l'Alumine (FRIA), a bauxite and alumina producer in the Republic of Guinea, and its Metals Research Laboratories in New Haven, Conn., were not included.

Magnesium-base	66	91			
Total	167,767	189,372			
Grand total	816,383	945,727			

[p] Preliminary.

[1] Aluminum alloys recovered from aluminum-base scrap in 1971, including all constituents, were 680,746 tons from new scrap and 189,412 tons from old scrap and sweated pig, a total of 870,158 tons.

[2] Aluminum alloys recovered from aluminum-base scrap in 1972, including all constituents, were 795,649 tons from new scrap and 213,255 tons from old scrap and sweated pig, a total of 1,008,904 tons.

Reynolds Metals Co., which had reacted to the 1970–71 oversupply situation by shutting down a large percentage of its primary aluminum capacity, was quick to react to the increase in market demand and reopened potlines at Longview Wash., Listerhill, Ala., and Troutdale, Oreg.

Secondary.—Recovery of secondary aluminum, calculated from reports to the Bureau of Mines, was 945,727 short tons, 15.8% above the 1971 level. Calculated recovery of all metallic constituents from aluminum base scrap increased 15.9% to 1,008,904 tons.

The Bureau estimated that full coverage of the industry would indicate a total scrap consumption of 1,342,000 short tons in 1972. Using this estimate, aluminum recovery totaled 1,045,000 short tons in 1972 and metallic recovery was estimated at 1,126,000 tons.

Construction by 1973 of a new plant to recover aluminum and other materials from the residues of a municipal incinerator at Lowell, Mass., was announced by Raytheon Co. The plant, costing $3.2 million, is to be 75% financed by the Environmental Protection Agency (EPA) and will get some support from State and city governments. The new facility was expected to treat 65,000 tons of residue per year and recover 1,000 tons of aluminum, 700 tons of zinc and copper, and 13,500 tons of colorless glass annually.

The city of Baltimore reportedly will build a $14 million solid-waste disposal plant that was expected to pay for more than 80% of its operating costs by the sale of reclaimed material. This plant was to be designed by Monsanto Enviro-Chem Systems, Inc., a subsidiary of the Monsanto Co.

The aluminum beverage can recycling programs of major primary producers, several beverage producers, and others continued to gain momentum. Industry estimates indicated that the number of aluminum cans recycled rose rapidly, from about 10 million in 1968 to 1.4 billion in 1972. Assuming an average of 22 cans per pound, these estimates translate to 230 tons recylced in 1968 and 33,000 tons recycled in 1972. Over 1,000 centers for the collection of aluminum cans, worth 10 cents per pound, were said to be located in 39 States.

A comprehensive study of the availability of metal (including aluminum), prepared by the Battelle Memorial Institute for the National Association of Secondary Materials Industries and EPA, was briefly reviewed.[4] Of the 2,215,000 tons of old and new aluminum scrap estimated by Battelle to have been available for recycling in 1969, only 48% was recycled, mostly in the form of new scrap. Of the total quantity of scrap that was available in that year, 60% was in the form of old scrap, of which only 13% was recovered. Collection was cited as the major problem in improving recovery from old scrap. Aluminum used in containers and packaging represented the largest portion of the unrecovered old scrap. Aluminum used in transportation and in consumer durables also was difficult to recycle because of the collection problem.

Alloys & Chemical Corp., an important producer of secondary aluminum alloys from purchased aluminum base scrap, closed its Cleveland, Ohio plant late in the year. The company, a subsidiary of Rio Tinto Zinc Corp, Ltd. of London, indicated that the closing was necessary mainly because of depressed market prices and the

[1] Excludes recovery from other than aluminum-base scrap.

lack of profits. The company's inability to invest in equipment to meet municipal standards for air pollution control also was cited as a factor.

Vulcan Materials Co. consolidated the operations of its secondary aluminum division with that of its metallics (detinning) division during the year. The new combined division will operate secondary aluminum facilities at Sandusky, Ohio, Milwaukee, Wisc., Hot Springs, Ark., and Corona, Calif., as well as the detinning operations of the company.

[1] Gross weight, including copper, silicon, and other alloying elements. Secondary smelters used 16,137 and 16,300 tons of primary aluminum in 1971 and 1972, respectively, in producing secondary aluminum-base alloys.
[2] No allowance was made for consumption or receipts by producing plants.

CONSUMPTION

Aluminum demand continued strong in 1972, and consumption, as measured by shipments of aluminum ingot and mill products to domestic users, surged upward by 16%. Total shipments including exports increased by 15%

The transportation market, representing the second largest market for aluminum products, gained about 24% over the previous year, and had the largest percentage and quantity increase of any of the major markets. The estimated average use of aluminum in 1973 model cars was about 78 pounds per unit. The engine block of the Vega continued to be made of aluminum, but its producer, General Motors Corp., indicated that there were no plans for using aluminum in any of its other models. The company indicated, however, that aluminum was still under active consideration for use in the Wankel rotary combustion engine, which could be first offered in U.S. automobiles as an option in the Vega.[5]

1969	3,821,001	−11,419	148,205	752,625	4,710,412
1970	3,878,920	−141,796	145,576	635,843	4,518,548
1971	3,887,429	[r] +396,408	[r] 167,030	[r] 648,138	[r] 5,099,005
1972	4,177,190	+466,765	188,594	755,762	5,588,811

[r] Revised.
[1] Crude and semicrude. Includes ingot equivalent of scrap imports and exports (weight multipied by 0.9).
[2] Aluminum content.

The first domestic application of the Wankel engine was announced.[6] Limited production of the new type engine (to power a snowmobile), which utilized about 35 pounds of aluminum in the form of castings for the rotary housing and for other parts, was begun by the Outboard Marine Corp. at Waukegan, Ill.

Building and construction with a 14% gain over 1971 shipments continued to be the largest market for aluminum products. Residential aluminum siding, the largest single use of aluminum in construction, gained markedly. The use of aluminum in mobile homes, the second largest use in construction, achieved only moderate market gains despite a large increase in the number of mobile homes built in 1972 (about 600,000 units) compared with the number built in 1971 (500,000 units).

As in past recent years the use of all aluminum beverage cans continued to show phenomenal growth. A report[7] indicated that the commercial use of the all-aluminum beverage can began in the early 1960's, reached 3.2 billion units in 1969, continued to rise to 6.4 billion units in 1971, and was 8.4 billion units in 1972. Based on an assumed requirement of 0.06 pound of aluminum can sheet per unit, the total quantity shipped for all aluminum beverage cans in 1972 was approximately 250,000 short tons, representing about 28% of the total container and packaging market, which included all-aluminum cans for beverages and other purposes, composite cans, and aluminum lids, flexible packaging, foil, etc.

According to a report by the BDC, the use of aluminum for nonaluminum purposes declined from 295,248 short tons in 1965 to 259,229 tons in 1971.[8] The quantities of primary aluminum used in 1965 and 1971 were 52% and 59% of the total, respectively. Secondary aluminum ingot and aluminum scrap, dross, and skimmings made up the remainder. The end-use distribution for nonaluminum purposes in 1965 and 1971 was as follows:

	Short tons	
	1965	1971
Steel deoxidizing and production of ferroalloys	169,781	124,943
Steel alloying		28,890
Steel coating		18,865
Zinc-base alloys	48,521	36,688
Copper-base alloys	4,053	8,723
Anhydrous aluminum chloride and catalysts	72,943	23,732
Other [1]		27,888
Total	295,248	259,229

[1] Includes magnesium-base alloys, other nonaluminum base alloys, explosives, pyrotechnics, exothermic applications, and miscellaneous chemicals.

A review of the nonaluminum uses of aluminum in the United States, analyzing the BDC data and presenting a technical description of the end uses was published.[9] The steel uses accounted for about 65% of the nonaluminum consumption. The total quantity used in steel in 1971 was 1.5% less than in 1965, but steel output in 1971 was 8% less than in 1965, indicating a probable increase in the unit use of aluminum in steel during 1965–71.

p Preliminary.

[1] Includes a small amount of rolled structural shapes.

[2] Includes a small amount of heat-treatable welded tube.

[3] Less than 0.1%.

STOCKS

Reflecting the strong upturn in demand, industry stocks of primary aluminum ingot at reduction plants declined from 174,966 tons revised at the beginning of the year to 120,465 tons at the end. Although all producers do not report stocks of aluminum at reduction plants to the Bureau of Mines, BDC reported that the total metal inventory held by the aluminum industry, which includes stocks of all metal forms at reduction and other processing plants, also declined. Total industry stocks of aluminum metal, including scrap, dropped from 2,510,066 tons at the beginning of the year to 2,401,859 tons at the end.

PRICES

The quoted price for 99.5% pure primary aluminum ingot at the beginning of the year was 29 cents per pound. However, in the early part of 1972 most sales reportedly were in the 20-to 22-cent-per-pound range. Demand increased during the year and market prices began to improve. By yearend some sales were believed to be as high as 24 cents per pound. In May the quoted price was dropped to 25 cents per pound to bring it closer to market conditions.

FOREIGN TRADE

Exports of crude and semicrude aluminum metal, including scrap, in 1972 were 12% higher than in 1971. Aluminum scrap exports were more than double those of 1971. and accounted for most of the increase. Exports of ingots, slabs, and other crude forms actually declined. As in past years Canada was the principal destination of U.S. aluminum exports, receiving 35% of the crude and semicrude aluminum exported, chiefly in the form of plate, sheets, and bars. Canada, Argentina, Japan, and Belgium-Luxembourg, in that order, were the principal recipients of ingot, slabs, and other crude forms.

U.S. imports for consumption of crude and semicrude aluminum increased dramatically for the second successive year, reaching 794,485 short tons, 15% above 1971 imports. Aluminum in the form of metal and alloys, ingots, and other crude forms, as in past years dominated imports, accounting for 83% of the total. Scrap imports declined sharply during the year to 52,301 tons. As in past years Canada was the principal source of U.S. aluminum imports, accounting for 77% of the ingot and other crude forms, and for 85% of the scrap imports. Other principal sources of imported ingot and other crude forms were Norway, Ghana, the United Kingdom, and France.

WORLD REVIEW

Despite predictions to the contrary, world aluminum demand surged ahead in 1972, increasing 10% above that in 1971. By yearend the industry's oversupply problem, which was at its worst in 1970 and 1971, appeared to be over as production gained 6.4% above the 1971 level. Capacity in several countries, which had been shut down in 1970–71, was reopened. In addition world production capacity at the end of 1972 was only 4% higher than at the end of 1971.

In response to the 1970–71 oversupply, the Organization for Economic Cooperation and Development (OECD) undertook a detailed study of world aluminum industry problems. The study included an analysis of world trends in demand, production, trade, stocks, prices, and costs and was expected to be released in 1973.

A report by the Organization of European Aluminium Smelters (OEA) described the economic development of the secondary aluminum industry in Europe and reviewed the secondary aluminum industry in the United States and Japan.[10]

The International Primary Aluminum Institute (IPAI), comprising some 50 member companies operating 130 primary aluminum plants throughout the world, was founded in April. The objective of IPAI was to publicize the properties of aluminum, promote new uses, collect statistics, study environmental problems, and make known the industry's accomplishments. The management of the institute, which established its headquarters in London, was largely delegated to a board of 12 directors, elected by the members for a 2-year term.

Argentina.—Construction of the 140,000-ton-per-year primary aluminum plant at Puerto Madryn apparently continued, but initial output was rescheduled to August 1974, 6 months behind the original startup date. Imports of aluminum metal were restricted to insure that imports met only established needs and did not result in increased inventories prior to the opening of the Puerto Madryn facility.

Bahrain.—The fourth and last planned potline at the primary aluminum plant of Aluminium Bahrain Ltd. was completed late in the year, bringing the plant's annual capacity to about 132,000 short tons.

Cameroon.—Domestic consumption of aluminum reportedly was 13% of production in 1968, 15% in 1969, and 21% in 1970.

Ceylon.—Long-range plans for a 7,500-ton-per-year primary aluminum plant to be expanded eventually to 20,000 tons per year reportedly were approved by the Government. Estimated demand for aluminum was believed to be about 10,000 tons per year.

China, People's Republic of.—Imports of aluminum metal have risen sharply in recent years, and totaled approximately 100,000 tons in 1972. One report attributed the increased demand to development of new hydroelectric power supplies and the concommitant requirement for electrical conductors made of aluminum.[11]

Egypt, Arab Republic of.—The 110,000-ton-per-year primary aluminum plant being built at Nag Hammadi, under a cooperative agreement with the U.S.S.R., was about half completed at yearend, but initial output was not expected until late in 1974.

Hungary.—A study by the National Technical Development Board forecast the consumption of aluminum in 1985 at 250,000 to 300,000 tons, equivalent to an average annual growth rate of 7%. The use pattern during the forecast period was expected to shift toward increased use of aluminum in the construction, agricultural, chemical, and packaging industries, whereas the growth rate of aluminum uses in the automobile, electrical, and domestic goods sectors was expected to slow somewhat.

Iceland.—The primary aluminum plant operated by the Icelandic Aluminium Co., Ltd. (ISAL) at Straumsvik was the first major industry to utilize the island's hydroelectric potential, believed to be about 1 million kilowatts. Production capacity of the ISAL smelter, which along with other users taps only 7% of the potential hydroelectric power, was expanded to about 83,000 tons per year at the end of 1972 by the addition of a 120-cell potline and a second alumina storage silo of 40,000 tons capacity.

India.—Output and capacity of primary aluminum continued to expand and further growth was planned. In the private sector, Aluminium Corp. of India, Ltd. (Alucoin) abandoned plans to expand its Asansol primary aluminum smelter by 3,800 tons by 1973 because of the shortage of power. This firm reportedly received Government approval for construction of a second aluminum smelter with an annual capacity of 16,000 tons at Rayagada, Orissa. Hindustan Aluminium Corp., Ltd. (Hindalco) completed a 17,000-ton-per-year expansion of its Rennkoot smelter in 1972 and was adding another 23,000 tons per year to be completed late in 1974. The Indian Aluminium Co., Ltd., had provisional approval from the Government to expand its Belgaum primary aluminum plant by 22,000 tons per year. Capacity of the Mettur primary aluminum smelter operated by the Madras Aluminium Co., Ltd., was expected to be raised to 28,000 tons per year by 1976.

In the public sector the Government, through its Bharat Aluminium Co., planned to construct a 110,000-ton-per-year primary aluminum plant at Korba, Madhya Pradesh, and a 55,000-ton-per-year plant at Koyna, Maharashtra. Operational dates of these two plants were scheduled for 1973 and 1975, respectively.

---

[11] Engineering and Mining Journal. More on Mainland China: A New Survey of Nonferrous Metals Industries. V. 173, No. 6, June 1972, p. 38.

Completion of all of the planned expansions would bring total aluminum production capacity to about 485,000 tons per year by the 1975–76 period, making the country self-sufficient in aluminum.

Indonesia.—Meetings were held during the year between Japanese and U.S. aluminum firms to discuss the possible construction and operation of a 220,000-ton-per-year primary aluminum plant in North Sumatra. Power for the plant was to come from hydroelectric facilities at Asahan. Participating companies reportedly included Nippon Light Metal Co. Ltd., Showa Denko K.K., Sumitomo Chemical Co. Ltd., Mitsubishi Chemical Industries, Ltd., Mitsui Aluminium Industry Co., Alcoa, and Kaiser. Financial arrangements for the power facilities and the time that construction of the power facilities would begin were not established at the end of 1972.

Iran.—The Iranian Aluminium Co. (IRALCO) began production of primary aluminum from its new 50,000-ton-per-year smelter at Arak in May, and the facility was officially opened in September. The plant, which utilized prebaked anodes, was scheduled to reach full production in March 1973.

Italy.—Alluminio Sardo-ALSAR, owned by the state organization Ente Participazione Finanziamento Industria Manifattura (EFIM) and Montecatini Edison S.p.A., was expected to begin commercial production of primary aluminum at its new 110,000-ton-per-year plant at Porto Vesme, Sardinia, early in 1973. A $500 million to $700 million electrochemical complex in Mazara del Vallo, Sicily was under construction by EFIM, Montecatini Edison, and another state organization, Ente Nazionale Idrocarburi (ENI), and was to include a 165,000-ton-per-year primary aluminum plant. The aluminum plant was expected to be operational by 1977 or 1978.

Japan.—Nippon Light Metal Co., Ltd., put into partial operation the first of two new potlines at its Niigata smelter. Full production on the first line was scheduled for 1973. The second line, which would raise capacity at Niigata to 153,000 tons per year, was to be brought in by 1974.

Mitsubishi Chemical Industries, Ltd., was reportedly considering an expansion at its newly completed Sakaide smelter. The project, to be completed in 1974, would add four new potlines, increasing capacity from 99,000 tons per year to 209,000 tons per year.

Furukawa Aluminium Co. (Furalco), owned by Alcoa (33.3%), Furukawa Electric Co. Ltd. (61.7%), and Nippon Light Metal Co. (5%), obtained Government approval to construct a 77,000-ton-per-year aluminum smelter in the Mikuni area of Fukui Prefecture in 1976. The $87.6 million smelter will use Alcoa's process for controlling fluoride emissions and will use purchased alumina from Western Australia. Ultimate capacity was set at 220,000 tons per year. Electricity will be supplied by a thermal power station jointly owned by Furalco and Hokuriki Power Corp. The smelter's output will be used in Furukawa's own fabricating plants.

Sumikei Aluminium Industries, Ltd., formed by the Sumitomo Group consisting of Sumitomo Light Metals Co. (40%), Sumitomo Chemicals Co. Ltd. (Sumika) (30%), Sumitomo Metal Industries (15%), Sumitomo Bank (5%), Sumitomo Trust and Banking (5%), and Sumitomo Shoji (5%), planned to construct a 99,000-ton-per-year aluminum smelter at Sakata, Yamagata Prefecture, scheduled to start production in October 1975. The plant eventually was expected to have a capacity of 200,000 tons per year. Electrical power was to be provided by a 350,000-kilowatt-capacity powerplant to be owned jointly by Sumikei Aluminium and Tohaku Electric Power Co.

Construction of the 82,000-ton-per-year primary aluminum plant planned by Kobe Steel Works, Ltd., for 1972 was postponed to mid-1976.

Korea, North.—The 1971 to 1976 development plan provided for a 20,000-ton-per-year aluminum plant but did not specify the type of plant. Some sources reported that three small primary aluminum plants were located in Hungnam, Chinnampo, and Tasado.

Korea, Republic of.—The Han Kuk Aluminium Co., which operates the only primary aluminum plant in South Korea, reportedly incurred financial difficulties and entered into an agreement with Péchiney Ugine Kuhlmann (PUK) whereby the capacity of the plant would be doubled to

36,000 tons per year by 1975. The new firm, to be jointly owned by Han Kuk and PUK, will be called The Daehan Aluminum Co.

Mexico.—Aluminio, S.A. de C.V., planned to increase annual capacity of its primary aluminum facility at Vera Cruz to 77,000 tons per year by 1975.

Netherlands.—Holland Aluminium N.V., jointly owned by Koninklijke Nederlandsiche Hoogovens en Staalfabrieken N.V. (Hoogovens) and N.V. Billiton Maatschappij (Billiton), acquired the one-third interest in the Aluminium Delftzijl N.V., 106,000-ton-per-year primary aluminum plant at Delftzijl, which was formerly owned by the Swiss Aluminium Co. (Alusuisse).

Papua.—A Japanese firm (Nippon Koei) was expected to survey port sites for the proposed Purari River hydroelectric project. The feasibility study of the project was expected to take 3 years and construction of a dam another 5 or 6 years. A primary aluminum plant was included in the long-range development plans.

Romania.—The primary aluminum plant at Slatina was being expanded to 220,000 tons per year. The expansion included four new potlines and was expected to be completed in 1975.

South Africa, Republic of.—Alusaf (Pty) Ltd. planned to increase production capacity at its Richards Bay primary aluminum plant to 82,000 short tons by the first half of 1974. The expansion was to be accomplished by addition of 66 new reduction cells to the existing 150 cells.

Taiwan.—Production capacity at the primary aluminum plant at Kaohsiung was expected to be increased to 77,000 tons per year by 1975.

United Kingdom.—Alcan (U.K.) Ltd. began initial production at its new Lynemouth primary aluminum plant in March. The plant uses alumina imported from Jamaica and eventually will use electric energy from its own 39,000-kilowatt, coal-fired powerplant nearby.

Yugoslavia.—Programs were continued to convert the country from an exporter of bauxite to an exporter of aluminum metal. The 55,000-ton-per-year primary aluminum plant under construction at Razine, near Šibenik in Croatia, was expected to begin initial production early in 1973. However, possible delay in construction of the electric power facilities could adversely affect future output.

TECHNOLOGY

Annual productivity of labor in domestic alumina reduction facilities between 1950 and 1972 has more than doubled, chiefly because of the use of larger reduction cells with better thermal characteristics and because of more careful control of operating conditions of individual cells. As shown in table 18, productivity in the aluminum industry has fluctuated at times and has been relatively unchanged during certain other periods. During the Korean War, productivity actually decreased from about 79 pounds per man-hour in 1950 to 73 pounds in 1953. During the next 2 years it increased rapidly to 93 pounds in 1955, but by 1957 it had increased to only 99 pounds. After 1957 it rose steadily to 152 pounds in 1962, and the rate of increase again slowed after 1963 to the 1969 level of 179 pounds per man-hour.

Aside from technologic improvements, a number of other factors apparently contribute to a decline in productivity or to a slowing down of the rate of increase. For example, an emergency condition or a period of rapid expansion of production facilities coupled with low utilization of capacity by established producers, or the entrance of new producers, historically has been accompanied by a decline or leveling off in productivity. During long-drawn-out periods of low-capacity utilization, such as that which occurred during 1970 and 1971, older, less efficient plants were shut down, and since relatively few new producers entered the field, overall worker productivity increased substantially. The high productivity in 1970 and 1971 is indicative of the improvement that can be expected in future years.

Alcoa announced the development of a new process for producing primary aluminum metal. In this process, which reportedly was developed after 15 years of research costing $25 million, alumina is reacted with chlorine to form aluminum chloride which is electrolyzed in a completely closed cell to produce molten alu-

Table 18.—Productivity in the aluminum industry [1]

Year	Production workers [2]		Production (thousand short tons)	Man-hours per ton of aluminum produced	Pounds of aluminum produced per man-hour
	Number (thousands)	Million man-hours			
1950	8.9	18.2	719	25.3	79

[e] Estimate.

[1] At primary aluminum plants only.

[2] U.S. Bureau of the Census. U.S. Census of Manufactures, 1954, 1958, 1963, and 1967. U.S. Government Printing Office, Washington, D.C. The figures for 1950–53, 1955–57, 1959–62, 1964–66, and 1968–71 represent estimates derived from a representative sample of manufacturing establishments canvassed in the Annual Survey of Manufactures.

minum metal and chlorine. The chlorine is recycled. The process reportedly operates at lower temperatures than present cells, which are based on a fluoride-containing bath, and uses 30% less electrical energy, lower labor input, and less space. The new process also eliminates the need to contain fluoride emissions. A 15,000-ton-per-year facility to determine the commercial potential of the new process was scheduled for operation in 1975.

The Bureau of Mines continued investigations of methods to recover aluminum from domestic nonbauxitic ores as an alternative to importing bauxite or alumina. Previous work had demonstrated the feasibility of producing aluminum-silicon alloys by smelting domestic aluminum silicate materials such as clay or anorthosite. In recent studies high-quality aluminum metal was produced from six aluminum silicon alloys, containing 20% to 87% aluminum, by electrolysis of the alloy in a molten bath of sodium, potassium, and aluminum chlorides, with or without fluorine.[12] Recovey of aluminum exceeded 80%, and metallurgical-grade silicon was found to be recoverable as a byproduct from the alloys containing 50% to 65% aluminum.

Soviet technology for producing primary aluminum metal and for casting aluminum ingots reportedly was purchased by three large international aluminum companies during 1972. Alcan Aluminium Ltd. (Alcan), licensed a process, presumably concerned with the utilization of electrical energy, which it said could significantly increase production efficiency at its facilities in Canada.[13] Reynolds Metals Co. and Kaiser Aluminum & Chemical Corp. obtained licenses to an electromagnetic process for casting large aluminum ingots which was said to produce a smooth finish on the ingot surface and eliminate the need for scalping or trimming the ingots before they are rolled into sheet or plate or extruded. The process also was believed to produce a better quality grain structure and reduce costs by as much as 1 cent per pound.[14]

In recent years the Bureau of Mines has greatly accelerated its investigations of methods to recover aluminum and other metals and materials from solid wastes.

[12] Singleton, E. L., R. L. de Beauchamp, and T. A. Sullivan. Recovery of Aluminum From Aluminum-Silicon Alloys. BuMines RI 7603, 1972, 12 pp.

[13] Metal Bulletin. Alcan Buys Russian Process. No. 5709, June 20, 1972, p. 14.

[14] Wall Street Journal. Reynolds Metals Sees Soviet Process in Use as Early as This Fall. V. 180, No. 40, Aug. 28, 1972, p. 11.

Two molten salt electrorefining processes to recover aluminum and to concentrate other metals into a recoverable form from electronic scrap were reported.[15]

Bureau research on recovery of values from municipal incinerator residues has progressed through the pilot plant stage. The methods developed will be further tested in a $3.2 million demonstration facility scheduled for completion in 1973 at Lowell, Mass. This plant was expected to treat 65,000 tons of residue per year and recover 1,000 tons of aluminum, 700 tons of zinc and copper, and 13,500 tons of colorless glass, annually. In 1972, the major Bureau effort was shifted to the development of new methods to mechanically separate aluminum and other metals and valuable materials from raw, unburned refuse. Research on this project was on a 5-ton-per-hour stage and included such operations as shredding, air classification, magnetic separation, screening, optical sorting, and high-tension electrostatic separation.

An experimental method was developed to recover aluminum and other materials from the nonmagnetic residue resulting when wrecked automobiles are shredded, passed over a magnetic separator, and hand sorted to remove large chunks of aluminum and other nonferrous metals. In commercial practice the nonmagnetic residue, which contains about 76 pounds of aluminum metal per ton and represents an annual loss of about 700,000 tons of aluminum and other metals valued at almost $40 million, is discarded. In the new method, a mixed metal concentrate containing 95% of the metals in the original reject material is recovered in a product that is 75% metal. This product is then washed with water to obtain a product that contains 99% metal. Separation of the aluminum and other nonferrous metals in this product was being investigated using cryogenic and heavy-media separation techniques.

The principal aluminum alloys produced, the raw materials used, and the problems and processes associated with the industrial recovery of aluminum from scrap were described in a comprehensive report.[16]

The technology and economics of controlling air emissions of gas and particulates from primary and secondary aluminum production operations continued to receive attention. A comprehensive study of air emission control technology and costs in the aluminum industry in the United States was prepared under contract to the EPA by Singmaster & Bryer, Metallurgical Engineers. Results of the study were summarized by an EPA official.[17] Based on an analysis of models representing the various plant processes and control systems in use in the aluminum industry, the contractor concluded that in 1970 overall fluorine control efficiency ranged from zero at plants without controls to an average of 94.7% at plants that utilized efficient systems to control fluorine emissions from potrooms as well as from the individual reduction cells. The average fluorine control efficiency in the industry was 73%, indicacting that about 23,500 tons of fluorine or 12 pounds per ton of aluminum produced in 1970 was emitted into the air. Of the total fluorine emitted, 46% was in a gaseous state, and the remainder was in a solid form.

The fluorine and dust control system installed at an alumina reduction plant at Lista in southern Norway was described.[18] The plant, which is 50% owned by Alcoa, utilized a duplex system whereby gas and particulate material, emitted from the reduction cells, are burned to oxidize the tar content and are then passed through single-stage cyclones to remove 30% of the dust in a fraction that contains most of the iron. The remaining gas and solids are passed through a fluidized bed of alumina which entraps 98.2% of the solids and absorbs 99.9% of the fluorine. The alumina, containing absorbed fluorine and entrained dust, is fed directly to the reduction cell. The potroom gas and dust that escape from the reduction cells during servicing operations are treated in wood scrubbing towers using sea water. This system removed about 90% of the fluorine from the potroom gas and 50% to 60% of the dust. Total emission of fluorine from another plant with similar control systems was 3 kilograms per hour, or about 1 pound per short ton of aluminum produced, based on a 30,000-ton-per-year output rate.

[17] Iversen, R. E. Air Pollution in the Aluminum Industry. J. Metals. v. 25, No. 1, January 1973, pp. 19–23.

[18] Eftestol, T., E. Morkesdal, and A. K. Syrdal. Duplex Gas Cleaning System at a Modern VS Soderberg Plant. Light Metal Age, v. 30, No. 5–6, June 1972, pp. 10–14.

One of the principal environmental concerns in the aluminum industry has been the prevention of air and water pollution from the chlorine used to flush oxides and gases from molten aluminum and to remove magnesium from aluminum-base scrap. The magnesium content of such scrap averages about 0.5% and must be reduced to about 0.1% for most casting applications. The historical method of removing gas from aluminum and magnesium from aluminum-base scrap (aside from diluting the magnesium-containing scrap with pure aluminum) has been to bubble chlorine gas up through the molten aluminum. The chlorine reacts with and flushes out various gases and also reacts with the magnesium. The resulting magnesium chloride rises to the surface of the melt where it can be skimmed off along with other products of the fluxing operation. Only about 5% to 10% of the chlorine reacts using this method, and the remainder is usually exhausted to the atmosphere. Several new methods for degassing molten aluminum alloys and for removing magnesium were developed which reportedly reduced the quantity of chlorine emitted into the air.

Reynolds Metals Co. used a mixture of gases containing 80% nitrogen and 10% each of carbon monoxide and chlorine to flush impurities from molten aluminum.[19] Another firm offered two methods to reduce chlorine pollution in fluxing molten aluminum.[20] One method utilized hexachlorethane tablets as a source of chlorine, and another utilized a mixture of a gas with 90% nitrogen and 10% chlorine.

In another process for cleaning liquid aluminum, the molten metal is treated with nitrogen gas in a degassing chamber and is then passed through a bed of coarse refractory granules, coated with flux to complete the cleaning operation, and finally passed through a bed of uncoated coarse granules to remove entrapped flux.[21] The process was said to eliminate the need for treating fumes in casting shops and to reduce operating costs, processing times, and metal losses from dross formation.

Alcoa developed a process whereby the magnesium in aluminium-base scrap is reacted with chlorine in stages in a closed system. The company reported that the stoichiometric reaction produced a 99% pure magnesium chloride as a byproduct.[22] Investment costs for processing 12,000 tons of aluminum alloy scrap per year using this method were estimated at $75,000.

Suggestions for selecting refractories and designing and constructing aluminum melting furnaces were given in a report.[23] The use of high-alumina refractories was recommended for use with molten aluminum furnaces to reduce silica migration, which increases wetting of and buildup on the furnace lining and reduces furnace volume.

The continuous hot dip method for applying an aluminum coating on steel to improve its corrosion and heat resistance has been in commercial use for many years, and in 1972 only one other process was in use on a large commercial scale. That method involved the electrostatic deposition of dry aluminum powder and was employed by the British Steel Corp. at Shotton in the United Kingdom. The hot dip process involves passing the steel strip through a molten aluminum bath at about 700° C. Formation of an iron-aluminum alloy at the interface of the steel base and the aluminum coating in this process adversely affects the formability of the material and limits its application. The dry powder process was envisaged as a means of avoiding this problem and a number of such methods were being developed.[24]

Antimony

By Charlie Wyche [1]

In 1972, domestic mine production of antimony, curtailed by a tragic fire at the Sunshine Mine, declined to the lowest level in more than 30 years. Secondary production also continued the downward trend from the 1969 high. The 18% increase in consumption of primary antimony, however, was supplied by a 75% increase in imports of ore, metal, and oxide.

The price of RMM brand antimony metal, in bulk, f.o.b. Laredo, Tex., was stable at 57 cents per pound throughout the year. The free world antimony price edged upward following buying interest from both consumers and dealers, and the People's Republic of China's reluctance to sell. The quoted price range of European lump ore, 60% antimony, declined during the first half of 1972 but reversed the trend in the second half and showed substantial strength at yearend.

Legislation and Government Programs.—Effective January 1, 1972, the General Modification of Tariff Schedules of the United States, Federal Register document 67-14749, filed on December 18, 1967 (Federal Register, v. 32, No. 244, Dec. 19, 1967, pp. 19002–19004, reduced the import duty on antimony metal TSUS No. 632.02 from 1.2 to 1.0 cents per pound. No further reduction is scheduled.

Under authorization of Public Law 92–105, enacted August 11, 1971, the General Services Administration (GSA) disposed of 70 tons of antimony from the Government stockpile in 1972. The total quantity authorized for disposal is 6,000 tons of "C" and "D" grades metal with a maximum of 800 tons to be sold each calendar quarter. All of the antimony was restricted to domestic consumption. Sales of the metal were in the form of granules, pigs, slabs, cakes, ingots, and broken pieces. All sales were made on an "as-is" basis and in keeping with its policy in stockpile sales, no warranties were made by GSA as to the chemical analysis, physical condition, or fitness for any use or purpose of the metal. Total Government inventory at the close of the year was 46,676 tons, of which 5,976 tons were surplus.

DOMESTIC PRODUCTION

MINE PRODUCTION

Domestic mine production from antimony ores and concentrates and coproduct antimony concentrates from silver mine production declined 52% to 489 short tons, the lowest level since 1953. Lead silver ores of the Coeur d'Alene district of Idaho contributed 345 tons, substantially below the 854 tons supplied in 1971. The drastic decline in production was due primarily to the 8-month closing of the Sunshine Mining Co., the only major domestic producer of antimony, following a disastrous fire in May. Tetrahedrite concentrates from Sunshine Mining Co., Hecla Mining Co., and Silver Dollar Mining Co. were processed into cathode metal, 96% antimony, at the Sunshine Mining Co. electrolytic plant. Byproduct antimony recovered at primary lead smelters from domestic lead ores totaled 516 tons. Most of this antimony was not recovered as the pure metal, but was processed to and consumed as antimonial lead.

The U.S. Antimony Corp. became a fully integrated mining, milling, refining, and sales organization. The company successfully completed a refining procedure to convert antimony sulfide concentrates to metallic antimony. Approximately 142 tons of antimony was produced in 1972, using this pollution-free process. In Nevada, one mine produced a small tonnage of antimony ore.

Table 2.—Antimony mine production and shipments in the United States

(Short tons)

Year	Antimony concentrate (Quantity)	Antimony	
		Produced	Shipped
1968	5,263	856	941
1969	5,707	938	943
1970	6,681	1,130	1,029
1971	4,721	1,025	1,073
1972	2,072	489	547

SMELTER PRODUCTION

Primary.—Production of 13,344 tons of antimony from primary ores at domestic smelters represented a 17% increase above that of 1971. The increase was essentially in production of oxide, and sulfide compounds, as metal production increased only slightly above that of 1971. Byproduct antimonial lead output dropped to 731 tons, 35% below that of the previous year. The source of feed materials for the smelter was as follows: 92% from foreign antimony ores and base metal ores, and 8% from domestic mine production of antimony concentrate and as byproduct at domestic lead smelters. Antimony recovered as a lead-smelter byproduct represented 7% of the total primary antimony production. Over 90% of the byproduct antimony produced at primary lead smelters was consumed at the smelter in manufacturing antimonial lead. A small quantity was processed to oxide or recycled in residues.

Primary smelter products were divided as follows: Metal, 29%; oxide, 63%; antimonial lead, 5%; and sulfide and residues, 3%. The NL Industries, Inc., smelter at Laredo, Tex., and the Sunshine Mining Co. electrolytic plant at Big Creek, Idaho, produced antimony metal. Oxide was produced by American Smelting and Refining Co., McGean Chemical Co., Harshaw Chemical Co., M & T Chemicals Inc., and NL Industries. Bunker Hill Co., American Smelting and Refining Co., St. Joe Minerals Corp., and U.S. Smelting Lead Refinery, Inc., were the principal producers of byproduct antimonial lead. McGean Chemical Co., Hummel Chemical Co., and M & T Chemicals Inc. produced antimony sulfide.

Secondary.—Secondary antimony recovery, from lead scrap, was slightly higher than in 1971. The increase was due chiefly to secondary lead plants as recoveries at primary lead smelters increased to about 61 tons. Manufacturers and foundries recovered 902 tons of antimony in processing scrap, 194 tons more than in 1971. Sources of old scrap, which supplied 85% of the secondary antimony, consisted of the following: Batteries, 70%; type metal, 17%; babbitt, 5%; and miscellaneous material, 8%. Drosses and residues resulting from manufacturing and casting operations provided 3,400 tons, or 15% of the total secondary antimony. Antimony in scrap is usually recovered as antimonial lead, with additions or removal of antimony as required in the refining stage to meet specifications for the various antimonial lead alloys. About 2,570 tons of primary antimony was used by secondary smelters to supplement the secondary supply during 1972, compared with 2,850 tons in 1971.

Table 3.—Primary antimony produced in the United States

(Short tons, antimony content)

Year	Class of material produced					Total
	Metal	Oxide	Sulfide	Residues	Byproduct antimonial lead

1969	24,741	1,174	729	179	2,082	8.4
1970	20,438	598	383	203	1,184	5.8
1971	19,686	828	304	59	1,191	6.0
1972	15,051	516	215	319	1,050	7.0

[1] Includes primary residues and a small quantity of antimony ore.
[2] Includes foreign base bullion and small quantities of foreign antimony ore.

CONSUMPTION AND USES

Industrial consumption of antimony in various end products totaled 38,624 tons, an increase of 12% above that of 1971. Primary antimony contributed 16,124 tons, 42% of the total, and secondary antimony, 22,500 tons. Secondary antimony was used predominantly in the manufacture of antimonial lead and other hard-lead alloys.

Consumption of primary antimony increased 18% in comparison to that of the previous year. Consumption increased for all classes of material consumed except byproduct antimonial lead. Antimony metal and antimony oxide represented 34 and 52%, respectively, of the material consumed, and antimonial lead about 5%. Consumption of primary antimony in metal products increased 11%, principally in that used for antimonial lead. Increases were reported for all products except ammunition, cable covering, solder, and type metal.

Nonmetal products required 23% more antimony in 1972 than in 1971. One of the largest uses was in flameproofing chemicals and compounds. Demand for flame-retardant materials increased when the U.S. Department of Transportation safety standard went into effect. This standard established specific flammability restrictions for interior components of passenger cars, trucks, and buses. In order to meet this requirement, automotive companies added various flame-retardant materials to their 1973 model interiors. Consumption in plastics, rubber products, and pigments also continued the upward trend. A total of 1,118 tons of antimony was consumed in "Other" nonmetal products. Three compounds, antimony sulfide, and potassium pyro-antimonate, with a wide range of applications, and sodium antimonate predominantly an opacifying agent in enamel and glass, accounted for 54% of the total. Approximately 19% was consumed as antimony chloride (pentachloride and trichloride), and the remaining 27% was used in a variety of chemical compounds.

Table 6.—Industrial consumption of primary antimony in the United States

(Short tons, antimony content)

Year	Class of material consumed						
	Ore and concentrate	Metal	Oxide	Sulfide	Residues	Byproduct antimonial lead	Total

STOCKS

Industrial stocks of primary antimony declined from the 9,740 tons at the end of the first quarter to a low of 8,481 tons at the end of the second quarter, increased to 9,130 tons by the end of the third quarter, and totaled 8,622 tons at yearend. Increases in oxide and sulfide stocks failed to offset decreases in metal, residues, antimonial lead, and ore and concentrates. Government stocks of antimony metal totaled 46,676 tons at the close of 1971. Of the total inventory, the strategic stockpile contained 24,645 tons and the supplemental stockpile contained 22,031 tons.

Table 8.—Industry stocks of primary antimony in the United States, December 31
(Short tons, antimony content)

Stocks	1968	1969	1970	1971	1972

[1] Inventories from primary sources at primary lead refineries only.

PRICES

The domestic price of antimony metal, 99.5%, RMM brand, and 99.8%, "Lone Star" brand, held at 57 and 68 cents per pound, respectively, in bulk, f.o.b., Laredo, Tex., (59 and 70 cents at New York). The dealer price for imported metal, duty paid, New York, also continued at 60 cents per pound. The domestic price of oxide continued unchanged at 69 cents per pound in carload lots.

At the beginning of the year, the quoted price of European lump ore, 60% contained antimony, at New York was $8.64 to $10 per short-ton unit. The price began to decrease in February due to lack of demand resulting from a slowdown in the U.S. economy. From February to August quotations were 25 to 30 cents per short-ton unit lower than earlier in the year. Prices eased in the second quarter and at yearend the quotation ranged from $7.60 to $8.60 per short-ton unit.

The GSA quoted prices for "C" (99.0%) and "D" (97.6%) metal were 54 and 51.5 cents per pound, respectively, f.o.b., designated Government storage locations.

Table 9.—Antimony price ranges in 1972

Type of antimony	Price per pound
Domestic metal [1]	$0.57
Foreign metal [2]	.535–0.57
Antimony trioxide [3]	.69–.77

[1] RMM brand, f.o.b., Laredo, Tex.
[2] Duty-paid delivery, New York.
[3] Quoted in Metals Week.

FOREIGN TRADE

Exports of antimony in alloys, metal, scrap, and waste totaled 121 tons and were valued at $84,800, only one-tenth the value of exports in 1971. Exports were destined for 12 countries. Canada, France, the United Kingdom, West Germany, and Chile, in declining order of receipts, accounted for 93% of the total. The quantity of antimony oxide exports increased to 311 tons valued at $276,600. Consignments were made to 15 countries. Canada imported 34% of the oxide, followed by West Germany and Taiwan with 33% and 13%, respectively. The remainder was divided among 13 other countries.

General imports of antimony of all categories totaled 23,743 tons (antimony content), a 75% increase from the 1971 deliveries and the highest level on record. The increase was essentially as antimony in ore and concentrate which increased from 22,100 to 33,500 tons gross weight. Oxide imports increased from 2,800 to 5,000 tons gross weight and metal imports from 1,700 to 2,400 tons. The Republic of South Africa and Bolivia supplied 59 and 15%, respectively, of the ore and concentrate imported. The People's Republic of China supplied almost half of the metal. The United Kingdom, Belgium-Luxembourg, and France supplied essentially all of the oxide imports (83%).

Additional imports included 129 tons of alloy containing 83% or more antimony by weight, 67% of which came from Mexico; 31 tons was received from United Kingdom; and 11 tons was supplied by Taiwan. Total value of this material was $136,314.

[1] Does not include alloy containing 88% or more of antimony; 1970—United Kingdom, 179 short tons ($378,740); Turkey, 18 short tons ($50,411); Japan, 13 short tons ($31,846); 1971—United Kingdom, 120 short tons ($120,093); Turkey, 32 short tons ($29,022); Japan, 22 short tons ($18,453); Mexico, 85 short tons ($113,319); Thailand, 11 short tons ($10,356); 1972—Mexico, 87 short tons ($79,294); United Kingdom, 31 short tons ($25,327) ;Taiwan, 11 short tons ($31,698).

WORLD REVIEW

World production in 1972 increased about 5,000 tons to a high of more than 75,000 tons. The most significant increase was in Thailand, which gained about 3,000 tons compared with 1971 production. Production increases were also reported in Mexico and Bolivia, which more than compensated for declines in output from the United States, Peru, Morocco, and Honduras.

The market was weak and demand was at a low level when the year began. A firming trend in world antimony prices began developing in midyear, and this trend continued throughout the remainder of 1972. The antimony industry was optimistic, based mainly on the use of antimony oxide for flame retardancy in the vinyl plastic field, especially in automotive applications. As a result, antimony producers around the world continued to develop new mines and to expand existing ones.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Antimony content of smelter products.

[2] Includes antimony content of antimonial lead.

[3] Data for 1970 are the sum of exports by small and medium mines and COMIBOL output; data for 1971 and 1972 reportedly represent total exports.

[4] 1970 and 1971 revised to zero.

[5] Antimony content of antimony concentrates, lead concentrates and lead-zinc concentrates.

Australia's Antimony Corp. N.L. placed the Dorrigo antimony mine in New South Wales on a production basis in view of the increased world market price of antimony concentrate. The company anticipates that prices will continue to firm as a result of projected improvement in the world economy, particularly in the United States. Production plans are for an output of about 4,000 tons per year of antimony concentrate representing gross annual sales of $2 million at the 1972 price level.

Munga Creek Minerals reported further work on the main shaft at the Munga Creek antimony mine at Kempsil, New South Wales. Following sublevel development, stoping was in progress, and a continuous supply of good ore has been assured. In the fourth quarter of 1972, the company produced 9,500 tons of antimony concentrate. Mill capacity will be doubled as soon as the main shaft comes into production.

An antimony plant came on stream in Italy. Azienda Minerali Metallici Italiani S.p.A. (AMMI) began operating its mine and metallurgical plant, at Manciano, near Grosseto. The antimony deposit contains an estimated metal reserve of 20,000 tons. Initial capacity of the plant has been scheduled at about 150 tons per year of metallic antimony.

In the Republic of South Africa at Consolidated Murchison Goldfields and Development Co. Ltd.'s plant, 547,000 tons of ore were milled during 1972, yielding 24,400 tons of antimony concentrate and cobbed ore. Although this output represented a 10% increase in the milling rate compared with that of 1971, the production of concentrate increased only marginally as the grade of ore mined was lower. To overcome this possible limiting condition on metal production, a decision was made in September to locate a new shaft, to be known as the Athens shaft, at the Weigel ore body. This ore body, which was mined and treated successfully at fairly shallow depths in the past, was selected in preference to the New Monarch ore body where preliminary work showed it to be more irregular. Working costs per ton milled were reduced by 12% compared with those of 1971. The increased milling rate could result in insufficient ore being available from the Alpha section of the mine by 1975.

In Bolivia, contracts for the structural steel to be used in the construction of the buildings housing a new antimony smelter were signed. Construction of the smelter is expected to be completed in 1975, with an estimated annual input capacity of 13,200 short tons of antimony concentrate averaging 60% antimony. This input quantity will result in a total annual output of close to 7,200 tons of antimony in the form of antimony trioxide. The patented process, developed in Czechoslovakia, to be used in the smelter is a system of volatilization and reduction of the antimony sulfide concentrate.

In 1972, Consolidated Durham Mines and Resources Limited began production at its Lake George area antimony property near Fredericton, New Brunswick, Canada. The mill has a capacity in excess of 400 tons per day; however, during 1972 production was maintained at 125 to 150 tons per day. Ore reserves at the 318-claim Durham Property were estimated at 150,000 tons, averaging 7% stibnite in two parallel veins.

TECHNOLOGY

One United States patent relating to the electrowinning of antimony from stibnite was issued during the year. U.S. patent 3,657,081, issued to W. C. Holmes on April 18, 1972, described a process in which concentrated stibnite ore is leached with a solution of sodium sulfide. The leached solution is electrolyzed in a diaphragm cell using the leach solution as the catholyte and stripped catholyte as the anolyte. A portion of the resulting oxidized anolyte is treated with chlorine gas to precipitate antimony and sulfur; the antimony precipitate is returned to the leaching circuit; and sufficient sulfur is discarded to maintain the sulfide sulfur concentration of the leaching solution at a predetermined level.

The results of the investigation of the metastable phases in liquid-quenched alloys of chromium and manganese with antimony,[2] and the transport and thermoelectric properties of compacts of bismuth and Bi–12 atomic percent antimony alloy powder were reported.[3]

Another important technical development during the year included a process for removal of surface antimony from antimony lead alloys by sulfuric acid-hydrogen peroxide pickling.[4] The surface antimony results from positive battery plates releasing a large proportion of their surface antimony during plate formation.

A recent development in the use of antimony with silver has produced a new brightening solution that adds hardness, exceptional brightness, and tarnish resistance in silver plating.[5] Called Techni-

[5] Skillings' Mining Review. V. 62, No. 5, Feb. 3, 1973, p. 15.

Silver E, the product allows an increase in amperage in the plating bath to 20 amperes per square foot of material, about double the usual level. The increased current density produces a plated item that requires no buffing or retouching after the plating process. The treatment increases tarnish resistance to about four times the amount usually found in silver plating.

An article published in 1972 on the flotation of stibnite from some Indian ores showed that the mineral could be floated after grinding through 48 mesh.[6] It could be floated easily at low pH with a mineral oil as collector and pine oil as frother. Stibnite could also be floated effectively with xanthates, provided the pulp is preconditioned with soluble lead or copper salts.

Asbestos

By Robert A. Clifton [1]

Shipments of asbestos in the United States increased less than 1% but established another record high in 1972. There was no readily apparent single reason that could explain the increased demand for asbestos. Imports were 8% above 1971 levels.

The world's largest producer, Canada, increased shipments to its largest market, the United States, by 10%; its total shipments were 3% over the 1971 total.

Legislation and Government Programs.—The Environmental Protection Agency (EPA) had not published its asbestos emission standards by yearend, but their latest proposal recognized the adequacy of Bureau of Mines controls in mines and mills and would only control visible emissions from mill effluent gases. In 1972 the General Services Administration (GSA) reduced government inventories by disposing of 1,040 short tons of amosite, 11,478 tons of crocidolite, and 656 tons of chrysotile. The strategic grades of asbestos formerly under the Rhodesian Sanctions began to appear again on the U.S. market.

Table 1.—Salient asbestos statistics

	1968	1969	1970	1971	1972

Subspecification	--	20	1,032	242	1,294
Crocidolite	None	1,554	23,890	--	25,444

Environmental Impact.—The expected effects of environmental regulations on the asbestos market were not apparent in 1972. The effect may just be postponed, because the Office of Safety and Health Administration (OSHA) of the Department of Labor did not promulgate its regulations until June 7, 1972, and EPA had not promulgated its regulation by yearend. The OSHA Threshold Limit Value (TLV) retained its previous emergency value of five fibers greater than 5 micrometers in length per milliliter. The five fiber TLV is scheduled for reduction to two fibers in 1976. This schedule might be shortened if union and activist pressures continue.

---

[1] Chemist, Division of Nonmetallic Minerals.

The final prepublication proposals for EPA regulations differed greatly from the originals as far as asbestos mining was concerned. The mines were omitted entirely as not needing EPA regulation, and the only standard applicable to mills pertained to "visible emissions to the outside air."

Some States, having written acceptable regulations, are now the environmental control regulating agency, with their regulations superseding, at least partially, those of the Bureau of Mines, OSHA and EPA.

DOMESTIC PRODUCTION

U.S. mines shipped less than 1% more asbestos in 1972 than in 1971. The value increased 10%. Four States produced asbestos; California, with 69%, was the leader, followed in order by Vermont, Arizona, and North Carolina.

The California segment of the asbestos industry continued to grow, with a 4% increase in production to 90,967 tons, and was led by the Pacific Asbestos Corp. mine in Calaveras County. The largest producing County was Fresno, with the Coalinga Asbestos Co., Inc., and Atlas Asbestos Corp. mines. Union Carbide Corp. had significant production in San Benito County. The State's increased production realized an $867,229 increase in value.

The GAF Corp. mine in Orleans County, Vt., remained the U.S. asbestos mine with the highest production and highest product value. With only the Jaquays Mining Corp. mine in Gila County operating again in 1972, Arizona production increased 2%. The production in North Carolina of Powhatan Mining Co. declined another 14% in 1972. U.S. asbestos producers and mine sites are as follows:

State and company	County	Name of mine	Type of asbestos
Arizona: Jaquays Mining Corp	Gila	Chrysotile	Chrysotile.
California:			
Atlas Asbestos Corp	Fresno	Santa Cruz	Do.
Coalinga Asbestos Co., Inc	do	Christie	Do.
Pacific Asbestos Corp	Calaveras	Pacific Asbestos	Do.
Union Carbide Corp	San Benito	Santa Rita	Do.
North Carolina:			
Powhatan Mining Co	Yancey	Hippy	Anthophyllite.
Do	Jackson	Boot Hill	Do.
Vermont: GAF Corp	Orleans	Lowell	Chrysotile.

NA Not available.

[1] Estimated by assigning Canadian values to all imports.

[2] Canadian shipment values.

[3] During these years Canadian production figures and values included "Asbestic" (tailings and short fibers), making extraction of an average fiber value impossible.

CONSUMPTION AND USES

In the 100th year of commercial asbestos use in the United States, some new definitive data on consumption have been collected. These data, because they were collected on a greatly revised form from an expanded list of consumers, bear no relationship to the estimates of previous years, and comparisons are inappropriate. They are shown in table 5. The chrysotile data in the table have been adjusted to reflect 95% of the apparent consumption. The other data are presented as reported.

It is no surprise that with a few thousand known end uses, 15% of consumption falls into minor categories or "Other." The eight major uses are construction 42%, floor tile 11%, friction products 10%, paper 9%, asphalt felts 6%, packing and gaskets 4%, insulation 2%, and textiles 1%.

Analysis of the newly available data on U.S. consumption of asbestos will be facilitated by some rather arbitrary combination of chrysotile grades. Table 4 shows these combinations, which disregard chemical variances, strength, electrical properties, and other differences other than uses based loosely on the Quebec Asbestos Mining Association standards. Crudes, and Groups 1, 2, while not milled, have the same ultimate textile uses as Group 3, and are combined as BM I (spinning). Groups 4 and 5 comprise BM II (shingle and paper). Groups 6 and 7 become BM III (shorts).

Note that the spinning grades (BM I) are found only in four of the major uses. These fibers comprised 3% of the reported tonnages. Shingle and paper grades (BM II) were 47% of the weight of the fibers reported and were in all the major uses but textiles. The remainder, 50% of the reported fibers, were shorts (BM III) and were found in every major use.

The construction field used 24% of the anthophyllite reported, and friction products used 29%. These were the only major uses reported, except for a tiny amount in textiles.

Seventy-two percent of the amosite reported was used for insulation, 18% for construction, and 6% for asphalt felts.

Construction accounted for 88% of the crocidolite and paper for 1%.

Overall consumption in 1972 increased nearly 7% over that of 1971, with no usage trends apparent.

PRICES

Quoted prices for Quebec asbestos in 1972 were unchanged since July 1, 1971. On January 1, 1973, British Columbia spinning grades were to rise 2% and cement grades 5%. The price of Arizona asbestos was expected to remain unchanged.

Prices for Arizona chrysotile asbestos have remained unchanged since August 1, 1968. Quotations, f.o.b. Globe, were as follows:

Grade	Description	Per short ton
Group 1	Crude	$1,410–$1,650
Group 2	do	700– 950
AAA		800
Group 3	Nonferrous filtering and spinning	425– 700
Group 4	Nonferrous plastic and filtering	400– 500
Group 5	Plastic and filtering	385– 425
Group 6	Refuse or shorts	250
Group 7	do	65– 90

As of January 3, 1973, Vermont Chrysotile asbestos, f.o.b. Morrisville, was priced as follows:

Grade	Description	Per short ton
Grade 4	Shingle fiber	$218.00–$371.00
Grade 5	Paper fiber	157.50– 185.00
Grade 6	Waste, stucco, or plaster fiber	114.00
Grade 7	Shorts and floats	43.50– 95.00

Quotations for Canadian (Quebec) chrysotile, f.o.b. mine, were as follows, as of July 1, 1971:

Grade	Description	Per short ton
Group 1	Crude	Can $1,615
Group 2	do	875
Group 3	Spinning fiber	412–675
Group 4	Shingle fiber	227–383
Group 5	Paper fiber	164–195
Group 6	Waste, stucco, or plaster	120
Group 7	Refuse or shorts	52–100

The increased demand for asbestos used in cement products (groups 5, 7) resulted in greater price increases in these categories. The last price rise for British Columbia emphasizes this point.[2]

Prices for British Columbia, Canada, chrysotile asbestos, f.o.b. Vancouver, will rise January 1, 1973 to the following:

Grade	Description	Per short ton
AAA	Nonferrous spinning fiber	Can $895
AA	do	711
A	do	541
AC	Asbestos cement fiber	388
AK	Shingle fiber	276
CP	do	261
AS	do	240
CT	do	235
AX	do	219
CY	do	155
AY	do	155

Privately negotiated sales are typical of the African asbestos producers. As this rules out market quotations, the following figures are averages, regardless of grade, of the values of South African imports calculated from U.S. Department of Commerce Data:

Type	Per short ton			
	1969	1970	1971	1972 [1]
Amosite	$153	$160	$164	$188
Crocidolite	189	196	212	222
Chrysotile	192	198	120	211

[1] First 8-month data on imports, U.S. Bureau of the Census.

FOREIGN TRADE

The value of exports of asbestos products manufactured in the United States increased 2 percent over the value of those exported in 1971. Five of the nearly 100 countries buying these products accounted for better than 60% of the foreign sales. They were Canada (44%), West Germany (9%), the United Kingdom (4%), Venezuela (2%), and Australia (4%).

In 1972 the United States imported 91% of its asbestos needs. This bettered the 1971 percentage, because of increased demand. Canada provided 97% of the imports, the Republic of South Africa provided 2%, and nine other countries, 1%. Chrysotile, with 98%, dominated the imported types. There was a near 10% increase in the dollar value of imported fibers. The Rhodesian values in table 7 reflect the recent lifting of the 1967 embargo.

WORLD REVIEW

Trend analyses such as those shown in figure 1 can reveal a great deal about the changes becoming apparent in the world market. The data were derived by using all the information available for the last 10 years to establish trends by linear regression analysis. The full 10-year figures were available for the United States and Canada, and at least 4 years were available for each of the other countries.

If each of the major consuming countries kept a near-constant share of an expanding market, the result would be a straight line, as shown by Canada. The U.S.S.R. and Japan typify those countries whose consumption rate has increased faster than the world production rate. The United States and the United Kingdom have gone the opposite way.

The United States, with a remarkably stable consumption rate, is taking a smaller share of the expanding market, and it is apparent that it will soon be supplanted by the U.S.S.R. as the world's largest consumer, if this has not already happened.

The same kind of analysis of Canadian data can also be informative, as shown in figure 2. Canada is both the world's largest producer and exporter of asbestos, and a major consumer as well. The marked divergence of the value and production lines shows graphically the inflationary trends. The upward slope of the production and export lines is indicative of the expanding world market. The slight divergence between the production and export lines illustrates that Canada's consumption growth rate exceeds that of production and that an increasing amount of Canadian asbestos is being used domestically.

Australia.—The Woodsreef mine and mill began operation in January 1972 and had such promising prospects that its parent Canadian company (formerly Pacific Asbestos) is now officially Woodsreef Minerals, Ltd. There was an official dedication in April and the mill was approaching full capacity throughout by yearend. This capacity (70,000 tons per year fiber) is felt to be inadequate, and plans for doubling it by 1975 are underway.

Bolivia.—The 3-year United Nations Development Program (UNDP) to assist in establishing an asbestos industry at Cochabamba was terminated in 1972. UNDP called the project a success and thought the operation could function without further assistance.

Canada.—The world's largest producer rebounded from last year's drop in production with a 3% increase in 1972. There were notes of caution from some industry leaders saying that market expansion would proceed at a slower rate and that new markets and applications were essential to a healthy industry. These probably well-founded views, however, were offset by the scurry of activity at producing mines and at those with potentials. This activity hints at a more optimistic viewpoint. Examples of this are—

1. The expansion and modernization of the Canadian Johns-Manville Co., Ltd., mine and mill at Asbestos, Quebec, has not been curtailed. The project neared completion at yearend, and among the new facilities was the world's largest crusher. This 800-ton gyratory crusher can accept the full load of a 200-ton dump truck at one time.

2. The Asbestos Corp's new mine on the Ungava Peninsula went into production and started shipping concentrate to Nordenheim, West Germany. Of real significance is the news that the tailings from

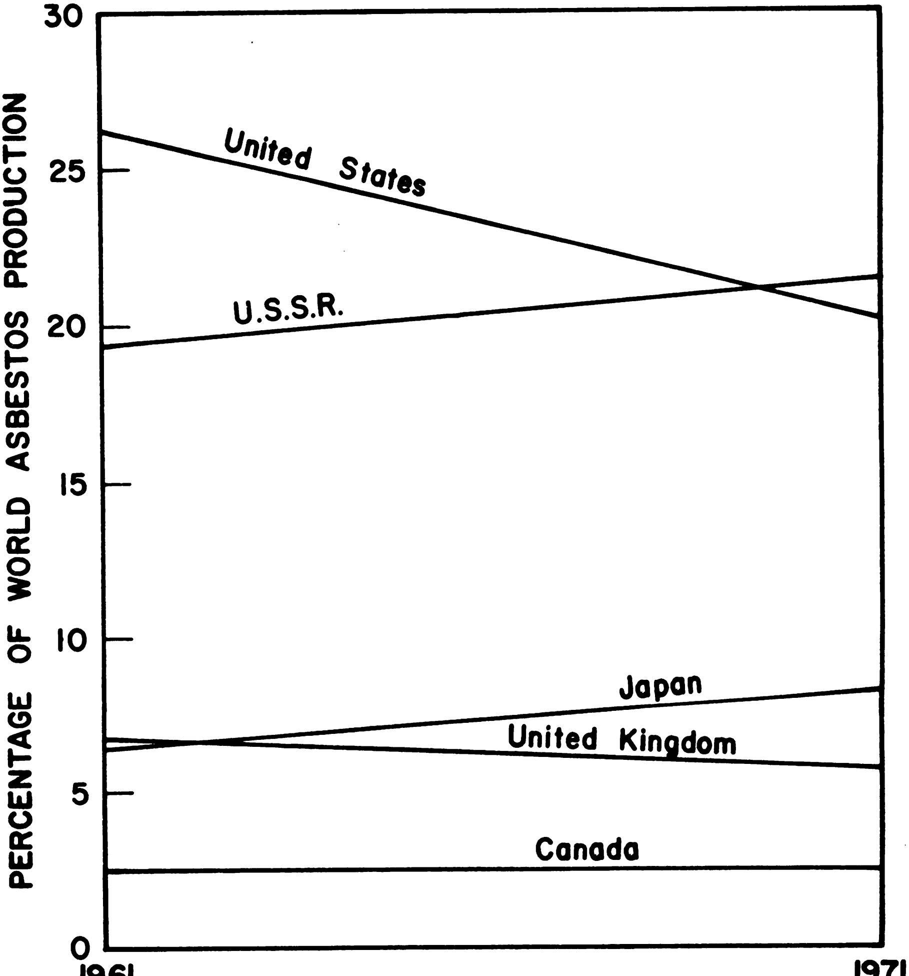

Figure 1.—National apparent consumption trends.

the Nordenheim plant are being used to make a marketable nonfired brick of good quality.

3. Abitibi Asbestos Mining Co., Ltd., has sold an 18% interest in its Amos, Quebec, deposit to Brinco, Ltd., which has an option on a further 33%. The $2 million advanced by Brinco is being used to provide a 35-ton-per-day mill for pilot studies.

4. Pan Ocean Oil Corp. is negotiating with Pathfinder Resources Ltd. over the possible development of an asbestos ore body in Cleveland Township, Quebec.

5. Allied Mining Corp. is planning a merger with United Asbestos Corp. to further the production plans for their Midlothian Township, Ontario, asbestos deposit.

New Zealand.—Kennecott Exploration Ltd., the New Zealand subsidiary of the U.S. company, has reportedly discovered a large asbestos property at Red Hills in West Otago on South Island.

Rhodesia Southern.—Undaunted by strikes early in the year, the Rhodesian and General Asbestos Corp. spent 25 million rand replacing the mill at their King mine. The first asbestos in several years was shipped to the United States.

Sudan.—A United Nations Development

Program survey of an asbestos deposit in the Ingenassa Hills has not yet been made public.

Swaziland.—The Government reached a new agreement with Turner & Newell Ltd. in which a 20% interest in the Havelock asbestos mine would be transferred to the Government immediately without cost and another 20% would be bought from profits over 6 years.

Barite

By Frank B. Fulkerson [1]

Domestic barite production totaled over 900,000 tons, an increase of 10% compared with 1971 output. Barite production in Nevada increased 65%. Imports of crude barite advanced 29% compared with those in 1971, which were below average because of a temporary surcharge on dutiable imports. Sales of ground and crushed barite produced from domestic and imported material rose 10% in quantity and 34% in value. Two barium-chemical plants were closed because of depressed market conditions.

DOMESTIC PRODUCTION

Barite was produced at 30 mines in seven States. Nevada supplied the largest tonnage, followed by Missouri and Arkansas.

Leading producing companies were Dresser Minerals, Dresser Industries, Inc., with mines in Arkansas, Missouri, and Nevada; Milchem, Inc., with four mines in Missouri and four in Nevada; Baroid Div., NL Industries, Inc., with two mines in Missouri, one in Arkansas, one in Nevada, and one in Tennessee; and Inlet Oil Corp., with a mine in Alaska.

---

[1] Industry economist, Division of Nonmetallic Minerals.

Ground and crushed barite was produced mainly in Arkansas, Missouri, and Nevada from domestic barite and in Louisiana and Texas from imported material. Processing plants were also located in Alaska, California, Georgia, Illinois, Tennessee, and Utah.

Dresser Minerals was constructing a new beneficiation plant at its Greystone mine, southeast of Battle Mountain, Nev. The new plant was scheduled for completion in 1973.

The Missouri Geological Survey test-drilled four tailings ponds in the Washington County barite district to determine the quantity and size-grade distribution of the barite contained in them. Interest in the ponds was increasing as known barite reserves were progressively being depleted. A district inventory indicated a total of 67 ponds containing an estimated 1.9 million tons of barite. This was equivalent to nearly 10 years' supply at the current production rate.[2]

CONSUMPTION AND USES

About 80% of the ground and crushed barite sold was used as a weighting agent in oil- and gas-well drilling muds; this use increased 139,000 tons. Barite usage for barium-chemical manufacturing decreased 35,000 tons. All other uses increased 18,000 tons.

Producers of barium chemicals from barite included Chemetron Corp., Huntington, W. Va.; Chemical Products Corp., Cartersville, Ga.; Great Western Sugar Co., Johnstown, Colo.; Inorganic Chemicals Div., FMC Corp., Modesto, Calif.; Mallinckrodt Chemical Works, St. Louis, Mo.; PPG In-

Total [4]	7	83,491	66,145	13,869,280

[1] Only data reported by barium-chemical plants that consume barite are included.
[2] Includes black ash, blanc fixe, chloride, hydroxide, oxide, peroxide, sulfide, and other compounds for which separate data may not be revealed.
[3] Black ash, 1 plant; blanc fixe, 2; chloride, 3; oxide, 1; peroxide, 1; and sulfide, 1.
[4] A plant producing more than 1 product is counted only once in arriving at total.

dustries, Chemical Div., New Martinsville, W. Va.; and Sherwin Williams Chemicals, Coffeyville, Kans.

PPG Industries closed the barium plant at its New Martinsville, W. Va., complex and went out of the barium-chemicals business, owing to depressed markets. Sherwin Williams Chemicals ceased the manufacture of barium carbonate at its Ashtabula, Ohio, plant, but continued to manufacture the product at Coffeyville, Kans.

Use of industrial minerals in oil-well drilling muds was reviewed.[3] Barite and bentonite are by far the most important from the viewpoint of sales value; a variety of other mineral commodities, including lime, soda ash, mica, gypsum, rock salt, and graphite, are also used. The position of barite for mud-weighting purposes seems secure as long as prevailing drilling methods continue.

PRICES

Prices of crude and ground barite generally are negotiated between buyer and seller. Prices of barite published in trade journals serve as a general guide and do not necessarily reflect actual transactions. Quoted prices for imported crude barite decreased in 1972.

The average value per ton excluding container cost of crushed and ground barite f.o.b. plant was $31.20 in 1972, compared with $25.58 in 1971.

Table 5.—Price quotations for crude and ground barite in 1972

Item	Price per ton
Chemical and glass grade, f.o.b. shipping point, carload lots, short ton:	
Hand picked, 95% $BaSO_4$, 1% iron	$22.50–$24.50
Water ground, 99.5% $BaSO_4$, 325 mesh, 50-pound bags	55–78
Drilling-mud grade:	
Ground, 83–93% $BaSO_4$, 3–12% iron, specific gravity 4.20–4.30, f.o.b. shipping point, carload lots, short ton	37–44
Crude, bulk, imported, specific gravity 4.20–4.30, c.i.f. gulf ports, short ton	14–18

Source: Engineering and Mining Journal.

FOREIGN TRADE

Canada and Singapore were the principal countries receiving natural barium sulfate and carbonate exports (mostly ground barite) from the United States. The exports increased from 24,000 tons in 1971 to 52,000 tons in 1972.

Imports of crude barite increased 29% compared with those in 1971. The increase can be attributed in large part to the removal of a 10% ad valorem surcharge that was in effect during the last half of 1971. Declared values of crude barite at foreign ports were as follows for the indicated countries: Ireland, $9.85; Mexico, $10.40; and Peru, $5.47. Imported barite was ground at processing plants in Louisiana and Texas. About 1,300 tons of crushed or ground witherite was imported from the United Kingdom.

Imports of precipitated barium carbonate rose over 600%. The large increase was due mainly to reduced domestic supplies of the chemical because of plant closures. West Germany supplied most of the precipitated barium carbonate. Imports of blanc fixe and barium chloride also increased appreciably.

WORLD REVIEW

Canada.—Barite output in Canada decreased owing to operating difficulties at the Walton mine, Dresser Minerals Division, Dresser Industries, Inc., in Nova Scotia. The mine flooded late in 1970, and the only production after that time has come from stockpiles and quarried material.

International Mogul Mines, Ltd., continued to evaluate the Lake Ainslie barite-fluorite deposits on Cape Breton Island in Nova Scotia. A preliminary economic appraisal indicated production of drilling-mud-grade barite and sub-acid-grade fluorspar from the deposits would be unprofitable.[4]

Indonesia.—IMCO Services, Division of Halliburton Co., was building a barite-grinding plant at Makassar. The plant was to be operational in 1973.[5]

Ireland.—Milchem, Inc., was constructing a barite flotation plant for treatment of the Irish Base Metals, Ltd., tailings pond in County Galway. Plant capacity was estimated at 60,000 tons of concentrate per year.[6]

Pakistan.—Following the discovery of large barite reserves in three outlying districts, the government of Baluchistan Province planned to build a barite-grinding plant at Khuzdar. The bulk of the output was to be exported.[7]

U.S.S.R.—A new 3,000-foot-deep central hoisting shaft was completed at the Atchisai lead-barite mining complex in southern Kazakhstan. The new deep shaft gave access to the troughs of the steeply folded synclines. The ore in the anticlines and flanks of the folds was being mined through the Mirgalimsay and Mirginskialie shafts.[8]

United Kingdom.—The United Kingdom imports about three-fourths of its barite requirements.[9] Morocco is the largest source. Imports, which currently total about 75,000 tons per year, are increasing rapidly because of exploration for oil and gas in the North Sea. Domestic barite production comes from mines in Derbyshire and Yorkshire. Production of witherite (natural barium carbonate) ended when the Settlingstones mine in Northumberland closed in 1969.

[3] Barite concentrates; total crude output reported as follows in short tons: 1970—114,270; 1971—153,110; 1972—153,000 (estimate).

[4] Ground barite; total crude output reported as follows in short tons: 1970—80,906; 1971—30,534; 1972—66,000 (estimate).

[5] Less than ½ unit.

[6] Year beginning March 21 of that stated.

TECHNOLOGY

A Canadian patent was issued on the froth flotation of barite or celestite ores. The aqueous pulp of ore was treated with the required reagents, including as an improved collector for the values, a fatty acid taurate amide of prescribed formula or a mixture of fatty acid taurate amides. The values were selectively floated in the froth.[11]

Bauxite

By Horace F. Kurtz[1]

World production of bauxite and alumina increased in 1972, but the increases were the smallest in recent years. The rate of growth in bauxite production was slowed because it had increased in 1970 and 1971 much faster than primary aluminum production, the principal end use for bauxite. Alumina production, the intermediate step between bauxite and aluminum production, has not increased as fast as bauxite output; however, in 1972 world alumina capacity was increased an estimated 13%. New alumina plants put into operation included two each in Australia and Japan and one each in Jamaica, Italy, and Hungary.

Bauxite and alumina production in the United States declined, but imports of alumina increased significantly.

Legislation and Government Programs.—About 586,000 long tons of Surinam-type metallurgical-grade bauxite sold in 1971 was removed from Government stockpiles during 1972. Jamaica-type bauxite was authorized for sale or exchange for other commodities needed to meet stockpile objectives, but none was sold.

Table 1.—Salient bauxite statistics

[1] Import figures for Jamaica, Haiti, and the Dominican Republic were adjusted by the Bureau of Mines to dry equivalent. Other bauxite imports, which are virtually all dried, are on an as-shipped basis. Excludes calcined bauxite and bauxite imported into the Virgin Islands.

DOMESTIC PRODUCTION

The production of bauxite in the United States declined 9% to 1.8 million long tons (dry equivalent) in 1972. Arkansas produced 90% of the total. Most of the remainder was mined in Alabama, and a small quantity was produced in Georgia. Except for the Mars Hill underground mine of Reynolds Mining Corp. in Saline County, Ark., all of the bauxite mines were open pit operations.

In Arkansas, Reynolds, Aluminum Co. of America (Alcoa), and American Cyanamid Co. mined in Saline County, and A. P. Green Refractories Co. produced in Pulaski County. Bauxite processing plants were operated in Arkansas by American Cyanamid, A. P. Green, Norton Co., Porocel Corp., and Stauffer Chemical Co.

Bauxite was mined in Barbour County, Ala., by A. P. Green, Eufaula Bauxite Mining Co., and Wilson-Snead Mining Co. In Henry County the producers were Abbeville Lime Co., Harbison-Walker Refractories Co., and Wilson-Snead. Drying or calcining facilities were operated by Eufaula Bauxite, Wilson-Snead, A. P. Green, and Harbison-Walker.

In Georgia, American Cyanamid operated two mines and a drying plant in Sumter County.

Reynolds Metals Co.:	
Hurricane Creek, Ark	840
Corpus Christi, Tex	1,385
Total	2,225
Grand total	7,760

[1] Capacity may vary depending upon the bauxite used.

The production of alumina and aluminum oxide products at the eight alumina plants in the continental United States and the plant in the Virgin Islands totaled 6.98 million short tons in 1972, a decline of 3%. The total production included 6.23 million tons of calcined alumina, 671,000 tons of commercial alumina trihydrate, and 70,000 tons of tabular, activated, and other alumina. The production of commercial alumina trihydrate increased 12% and reached a level more than double the output in 1968.

Shipments of alumina were 6.97 million tons, valued at $497 million. Approximately 6.02 million tons were shipped to primary aluminum plants. The chemical industry, including the producers of aluminum fluoride fluxes for aluminum plants, received the second largest tonnage, and most of the rest of the alumina was shipped to producers of abrasives, ceramics, and refractories.

CONSUMPTION AND USES

The consumption of bauxite in the United States (including the Virgin Islands) in 1972 decreased 2% to 15.4 million long tons (dry basis). Most of the decline resulted from lower production of calcined alumina for the aluminum industry. About 87% of the bauxite consumed was imported ore.

The production of alumina and related products accounted for 93% of the total bauxite consumption. An average of 2.13 long dry tons of bauxite was used to produce 1 short ton (calcined basis) of alumina. The two alumina plants in Arkansas were based mainly on the use of domestic bauxite, and the other seven alumina plants used only imported ore.

Bauxite consumption by the refractories industry reached a record high level of over 400,000 long tons (dry basis). Nearly all of this bauxite was used in the calcined form, and 82% was imported, mainly from

Table 7.—Bauxite consumed in the United States, by industry

(Thousand long tons, dry equivalent)

Year and industry	Domestic	Foreign	Total[1]

W Withheld to avoid disclosing individual company confidential data, included with "Chemical."

[1] Data may not add to totals shown because of independent rounding.

[2] Includes consumption by Canadian abrasive industry.

[3] Includes other uses.

Guyana. The use of bauxite for the manufacture of refractories has increased every year but one since 1958 when consumption was 60,000 tons.

The use of bauxite to make artificial abrasives also increased in 1972 to about the average level of the past decade. All of the bauxite used by the abrasives industry was calcined. Most of the ore came from Surinam, and the remainder came from Australia and Guyana. Data on consumption by the abrasives industry included bauxite fused and crushed in Canada since much of this material is made into abrasive wheels and coated products in the United States.

Chemical producers decreased their consumption of bauxite by 11% during the year. Other consumers of bauxite, in descending order of magnitude, included the cement, oil and gas, and steel and ferroalloys industries, and municipal waterworks.

Table 8.—Crude and processed bauxite consumed in the United States in 1972

(Thousand long tons, dry equivalent)

Type	Domestic origin	Foreign origin	Total [1]
Crude	1,748	6,857	8,604
Dried	18	5,981	5,998
Activated	7	--	7
Calcined	178	588	765
Total [1]	1,950	13,425	15,375

[1] Data may not add to totals shown because of independent rounding.

Calcined alumina consumed by the 30 primary aluminum plants in the United States totaled 7.94 million short tons, an increase of 5.6%. Alumina consumption data for other uses were not available. A significant quantity was used to make aluminum fluoride and synthetic cryolite, which is also used in the production of primary aluminum.

Source: Data are based upon Bureau of the Census report Form MA–28E.1, Annual Report on Shipments and Production of Inorganic Chemicals.

STOCKS

Consumers inventories of bauxite increased during the year, but stocks at mines and processing plants declined sufficiently to account for a net decrease of 3% in total industry inventories. Government stockpiles were reduced 4%. About 586,000 long tons of Surinam-type bauxite was shipped from Government defense inventories and an additional 110,000 tons of bauxite was shipped from a Government stockpile accumulated during World War II.

Total inventories of alumina and related products at plants producing alumina and primary aluminum were 1,079,000 short tons on December 31, 1972, virtually unchanged from 1971 yearend stocks.

Table 10.—Stocks of bauxite in the United States [1]

(Thousand long tons, dry equivalent)

Sector	Dec. 31, 1971 [r]	Dec. 31, 1972
Producers and processors	997	786

Government [2]	17,149	16,453
Total	20,813	20,008

[r] Revised.

[1] Domestic and foreign bauxite; crude, dried, calcined, activated; all grades.

[2] Includes bauxite stockpiled during World War II (891,000 tons Dec. 31, 1971, 781,000 tons Dec. 31, 1972) plus bauxite in defense material inventories (national stockpile, supplemental stockpile, Defense Production Act).

PRICES

Market prices for domestic crude (undried) and dried bauxite were not published. Bureau of Mines estimates of the value of bauxite production were based on data supplied by producers. Data for most of the crude bauxite came from companies which produce bauxite for their own use rather than for sale. The Bureau estimated the average value of crude domestic bauxite shipments in 1972, f.o.b. mine or plant, at $10.60 per long ton. The average values of shipments of domestic dried and calcined bauxite were estimated at $14.39 and $3.38 per ton, respectively. Bauxite values among producers varied widely because of differences in grade. The average value of imported dried or partly dried bauxite consumed at domestic alumina plants was estimated at $14.79 per long dry ton, compared with $14.39 (revised) for 1971. During 1972, Engineering and Mining Journal published the following prices on refractory-grade bauxite, carlots, Atlantic ports, per long ton:

	January–September	October–December
87.75% minimum Al_2O_3	$47.50	$47.50
88% Al_2O_3 (super calcined)	51.00	60.50

Table 11.—Market quotations on alumina and aluminum compounds

[1] Excludes bauxite into the Virgin Islands from foreign countries 1970—Australia $4.91, Guinea $4.51; 1971—Australia $5.54, Papua (New Guinea) $4.31, Guinea $4.94; 1972—Australia $4.74, Guinea $4.82, Guyana $7.01.

[2] Less than ½ unit.

[3] Dry equivalent tons adjusted by Bureau of Mines used in computation.

Note: Bauxite is not subject to an ad valorem rate of duty, and the average values may be arbitrary for accountancy between allied firms, etc. Consequently, the data do not necessarily reflect market values in the country of origin.

The average value of calcined alumina shipments, as determined from producers reports, was $65.60 per short ton. Shipments of alumina trihydrate averaged $76.67 per ton. The average value of imported alumina (including small quantities of aluminum hydroxide) was $60.85 per ton at port of shipment. Exports of alumina from the United States and the Virgin Islands averaged $71.67 per ton.

FOREIGN TRADE

Exports from the United States classified as "bauxite and concentrates of aluminum excluding alumina" totaled 29,000 long tons and were valued at $1.3 million in 1972. Canada received 13,000 tons, with an average value of $60.87 per ton, and Japan received 12,000 tons, with an average value of $14.10 per ton.

Exports of alumina, including 41,000 tons of aluminum hydroxide, declined 19% to 879,000 short tons. Most of the decline resulted from reduced shipments to the U.S.S.R.; however, Canada and the U.S.S.R. remained the largest recipients. Additional shipments of 275,000 tons of alumina were made from the Virgin Islands to foreign countries.

Aluminum sulfate exports, which were shipped mainly to Canada and Venezuela, totaled 5,000 tons and were valued at $181,000. Exports of artificial corundum or fused aluminum oxide totaled 18,000 tons and were valued at $7.25 million. Canada received 7,000 tons. Exports classified as "other aluminum compounds" totaled 45,000 tons and were valued at $10.5 million. Much of this tonnage was believed to be aluminum fluoride and synthetic cryolite shipped to primary aluminum plants in other countries.

No duties were imposed on imports of bauxite, alumina, or aluminum hydroxide in 1972. All duties on these commodities were suspended effective July 15, 1971.

Imports of crude, partially dried, and dried bauxite decreased for the second consecutive year to 11.4 million long tons, as receipts from all of the four largest supplying countries declined. The decrease of 9% from the record high year of 1970

[1] Includes small quantities of aluminum hydroxide previously not included.
[2] Less than ½ unit.

Note: Shipments from the Virgin Islands to the United States: 1970—119,000 short tons ($9,550,000); 1971—120,000 short tons ($9,316,000); 1972—67,051 short tons ($4,827,674).

was attributed to a reduction of domestic stocks of bauxite, increased imports of alumina, and a slowing down in the growth of primary aluminum production during this period. Bauxite imports into the Virgin Islands also declined from a record level reached in 1971.

Calcined bauxite imports into the United States fell 15% to 247,000 tons, reflecting decreased receipts of refractory-grade bauxite from Guyana. Except for 6,000 tons received from Australia, all of the calcined bauxite originated in Guyana or Surinam.

Imports of alumina, including small quantities of aluminum hydroxide, increased 18% to 2.85 million short tons. Receipts from Jamaica alone increased nearly 300,000 tons as new alumina capacity owned by United States aluminum producers came onstream. Australia provided 41% of the total imports, Jamaica 26%, and Surinam 20%.

WORLD REVIEW

World production of bauxite increased 4% in 1972. Australia, the largest bauxite-producing country, showed the greatest increase, and Australia and Jamaica together produced over 40% of the world's supply. Bauxite production in Guyana and Greece declined appreciably, but future output in these countries was expected to increase.

World alumina production registered a small increase, however, Jamaica's output gained 18%. The United States produced 27% of the world's alumina, declining steadily from 35% in 1969.

Australia.—Alcoa of Australia (W.A.) N.L. continued production of alumina at its Kwinana plant 20 miles south of Perth, Western Australia, and in May began production at a new plant at Pinjarra, about 50 miles south of Perth. The initial annual capacity of the first two units at the Pinjarra plant was 463,000 short tons and reportedly cost over $50 million. The plant

Total	[r] 56,873	62,506	64,795

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Southern Rhodesia may have continued to produce bauxite during the period covered by this table, but no information on bauxite mining activities, if any, are available since 1965.

[2] Dry bauxite equivalent of crude ore.

[3] Exports.

[4] Dry bauxite equivalent of ore processed by drying plant.

[5] Bauxite processed for conversion to alumina in Jamaica plus exports of kiln dried ore.

[6] Previous year table indicated metal content.

[7] Excludes materials other than bauxite used for the production of alumina, estimated as follows in thousand long tons: nepheline concentrates (25 to 30% aluminum)— 1970, 390; 1971, 490; 1972, 590; alunite ore (16 to 18% aluminum)—1970, 195; 1971, 295; 1972, 295.

[8] Diasporic bauxite for production of aluminum only; excludes 98,000 to 195,000 tons of production for refractory applications.

[9] Less than ½ unit.

was to be increased to 880,000 tons by the end of 1974 and eventually to a capacity larger than that of Kwinana. Both alumina plants use bauxite from the Darling Range, and reserves have been estimated to be on the order of 500 million tons. The Pinjarra plant is supplied by a 4-mile conveyor belt from the Del Park deposit. Alcoa's deposits and the mining and treatment of bauxite from Del Park were described.[2]

American Metal Climax, Inc. (AMAX), postponed the development of its proposed bauxite-alumina complex in the Kimberley area, Western Australia, and announced the signing of a contract to purchase an additional 440,000 tons per year of alumina from Alcoa's plant at Pinjarra beginning in 1975. The Government of Western Australia extended the effective dates on the Kimberly bauxite claims of Amax Bauxite Co. to 1984 so that the development of this project could be reconsidered under different marketing and financing conditions. The postponement was attributed to difficulty in financing the project through an international consortium on a scale large enough to be economical.

Comalco Ltd. completed a 2½-year expansion program to increase its capacity to produce and ship bauxite from Weipa, Queensland, to 10.5 million tons per year. Estimates of bauxite reserves in the Weipa field range from 2.2 to 2.5 billion tons. Comalco reported that it had opened a new mining area at Andoom, about 12

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Austria produces alumina (fused aluminum oxide) but output is used entirely for abrasives production. Production was as follows in short tons: 1970—30,354; 1971—30,011; 1972—28,943.

miles south of Weipa. Bauxite production was increased to 7.6 million long dry tons in 1972. Shipments declined to 6.9 million tons of beneficiated bauxite, of which 3.0 million tons were shipped for processing to alumina in Australia, 1.8 million tons to Japan, and 2.1 million tons to Europe and other countries. Shipments of calcined bauxite for use in making aluminous abrasives increased.

Comalco's Bell Bay alumina plant continued to operate at its capacity of 65,000 short tons of alumina. Construction of the third phase of expansion at the Gladstone plant of Queensland Alumina Ltd. was delayed by work stoppages. At yearend the expansion was expected to be completed by the third quarter 1973, at which time the alumina plant, the largest in the world, should have a rated annual capacity of 2.24 million tons. Production at Gladstone in 1972 increased 3% to 1.5 million short tons.

In July, Nabalco Pty., Ltd., brought into production its new alumina plant at Gove in Arnhem Land, Northern Territory. Nabalco is the managing company of the joint venture of Swiss Aluminium Australia Pty., Ltd. (70%), and Gove Alumina Ltd. (30%). Colonial Sugar Refining Co. is majority shareholder of Gove Alumina. The new refinery has an initial rated annual capacity of 560,000 short tons, which is to be doubled. Bauxite reserves in the Gove area are reportedly over 250 million tons. The Gove operations and the evolution of the project were described.[3]

The plant site at Upper Swan in the suburbs of Perth, where Pacminex, Pty., a subsidiary of Colonial Sugar Refining had planned to construct an alumina plant, was vetoed by the Government for environmental reasons. A new plant site at Muchea, 30 miles north of Perth, was subsequently agreed upon. This Pacminex venture was reported to include Hanwright Minerals, Ltd., and Metals Miniere, Ltd.

Brazil.—Since 1969, Mineração Rio do Norte, S.A., a subsidiary of Alcan Aluminium Ltd. (Alcan), has been developing deposits of several hundred million tons of low-silica bauxite between the Amazon and Trombetas Rivers. Alcan announced deferment of the project in mid-July, but by December 1972 Alcan signed an agreement with Companhia Vale do Rio Doce

---

[3] Metal Bulletin Monthly. Bauxite the Life History of Gove. No. 22, October 1972, pp. 38–41.

(CVRD) for a joint study of the project. Since previous geologic examination has confirmed the existence of sufficient reserves of good quality bauxite close to navigable river transportation, the principal problems will be markets and financing. Other large bauxite deposits are indicated south of Belem in the Paragominas region.

Cameroon.—Economic and technical studies of the bauxite deposits near Minim-Martap in the Adamawa Range were being conducted by Société d'Etudes des Bauxites du Cameroun (SEBACAM), an association formed by the Government, Péchiney Ugine Kuhlmann (PUK), Kaiser Aluminum and Chemical Corp., and Vereinigte Aluminium Werke. The studies, which were to be completed by 1974, will report on the feasibility of a large-scale bauxite exporting enterprise and the possibility of producing alumina. Estimates of reserves in the Minim-Martap area have been on the order of 1 billion tons. The deposits are about 350 miles inland from the coast near a section of the Trans-Cameroon Railway scheduled for completion by 1975. The studies will include evaluation of the various possibilities for transporting the ore, the selection and construction of a deep-water port, and the development of the bauxite deposits. The geological field work was reported to have been completed.

Canada.—Alcan installed a new dryer circuit at its Arvida, Quebec, facilities for the production of 100,000 tons per year of alumina hydrate. Most of the hydrate was expected to be used in fire retardant carpet backing.

China, Peoples Republic of.—Trade reports indicated that the People's Republic of China was increasing its exports of calcined refractory-grade bauxite. The material was believed to contain alumina mainly as the mineral diaspore, and iron specifications were quoted at a maximum of 2% Fe_2O_3.

Fiji.—Bauxite Fiji Ltd., owned by three Japanese aluminum producers, continued construction of bauxite producing facilities on the island of Vanua Levu. Initial bauxite shipments, which had been scheduled for the second half of 1972, were postponed because of construction delays.

Ghana.—In June, The Government issued a license to prospect the bauxite deposits near Kibi to Bauxite Alumina Study Co., Ltd., (Bascol). Bascol was owned by Kaiser (50%), Reynolds Metals Co. (30%), and Aluminum Resources Development Co. (Ardeco) (20%). Ardeco is a consortium of five Japanese aluminum companies. Reynolds withdrew from Bascol at the end of the year. The initial studies begun in 1972 were to determine whether a full feasibility study of a bauxite-alumina complex should be undertaken.

The Government announced its intention to obtain 55% participation in foreign mining investments. The new program presumably would apply to the operations of British Aluminium Co., Ltd., at Awaso, the only active bauxite mines in Ghana, and to any new bauxite mining ventures.

Greece.—A new concentrator for low-grade bauxite was put onstream by Bauxites Parnasse S.A. on June 25 at Itea. The new plant will treat low-grade bauxite previously considered uneconomic by extracting limestone and clay impurities from the ore. The process will make possible large-scale underground operations. Over $15 million have been spent, and about $7 million are allocated to finish the expansion program. The company's bauxite reserves are estimated at about 500 million tons.

Aluminium de Grèce S.A. reportedly was increasing its alumina production capacity about 6% through an $8 million plant expansion. Aluminium de Grèce acquired the assets of the Bauxitai Distomon S.A. mining company, reported to have extensive bauxite reserves.

PUK announced intentions to build a 1-million-ton-per-year alumina plant in Greece which would be independent of Aluminium de Grèce (90% owned by PUK). A preliminary agreement was reached between Alcoa and the Greek Government for construction of a new complex with initial annual capacities of 330,000 tons of alumina and 165,000 tons of aluminum metal. Plans for financing by the U.S.S.R. of a 495,000-ton-per-year alumina plant were announced by a group of local businessmen. The Soviet Government would take the total plant output for 7 years to retire the loan.

Early in 1972 the Greek Government announced a bauxite export quota of 1,275,000 tons, down 20,000 tons from the quota for 1971. The principal quotas set were: European Economic Community, 420,000 tons; U.S.S.R., 450,000 tons; Great Britain, 100,000 tons; United States, 75,000 tons; Japan, 20,000 tons; Czechoslovakia, 20,000 tons; Sweden, 70,000 tons; Spain, 60,000 tons.

Guinea.—Bauxite and alumina were produced by Compagnie International pour la Production de l'Alumine (FRIA), an international consortium in which Olin Corp. is the largest shareholder.

Guinea Bauxite Co. (CBG) continued construction of mining and ore preparation facilities and infrastructure for the Boké bauxite project. CBG is owned by the Government of Guinea (49%) and Halco Mining, Inc. (51%), a consortium consist-

ing of Alcoa (27%), Alcan (27%), Martin Marietta Aluminum, Inc. (20%), PUK (10%), Vereingte Aluminium Werke A.G. (10%), and Montecatini-Edison S.p.A. (6%). The first shipment of bauxite has been rescheduled for the second half of 1973. Shipments were expected to be made initially at the rate of 4.7 million tons per year and increase to 8 million tons by the third year. The railroad from the mining site at Sangaredi to the port town of Kamsar has been completed. Three drying kilns and facilities for calcining abrasive-grade bauxite are located at Kamsar. At yearend CBG was attempting to raise $60 million in bonds and notes for the Boké project. This would increase the total funds made available for Boké to over $320 million, including $73.5 million in World Bank loans.

The Government, with assistance from the U.S.S.R., was developing a bauxite deposit at Debele in the Kindia region. Reserves were estimated at 44 million tons. The project included construction of a railway link for transporting the bauxite to Conakry, and shipments to the U.S.S.R. were expected to begin by the end of 1974.

Guyana.—The Government-owned Guyana Bauxite Co. (Guybau) closed its alumina plant for 7 weeks during the summer of 1972 because of market conditions. Sales of better than 250,000 tons of alumina included about 100,000 to the U.S.S.R. and 30,000 to the People's Republic of China. The first full year of production since the facilities were nationalized in 1971 was regarded as satisfactory by Guybau, considering the weak world market for metallurgical-grade bauxite and alumina.

Hungary.—Bauxite exports were estimated at 700,000 tons in 1972. As part of Hungary's long-term plans for expansion of its bauxite and alumina production, a new mine was opened in the Halimba area north of Lake Balaton in the Bakony Range. Reported to be the largest and deepest bauxite mine in central Europe, the new mine is expected to reach an annual production rate of 600,000 tons by 1973.

A new alumina plant, the second at Ajka, began production in 1972 and was expected to operate at an annual capacity of 265,000 short tons by the end of 1973. Planned alumina production for Hungary in 1973 is 770,000 tons (compared with 294,000 tons in 1965).

India.—Construction of the 220,000-ton-per-year alumina plant at Korba, Madhya Pradesh, being built by the Government-owned Bharat Aluminium Co., was reportedly delayed by shortages of steel and imported equipment. The plant was 90% completed at yearend, and the new date for initial production was April 1973.

Indonesia.—P.T. Alcoa Minerals of Indonesia continued exploration of the potentially important deposits it has located in southwest Kalimantan (Indonesian Borneo).

Italy.—The construction of a 660,000-ton-per-year alumina plant in Sardinia for Eurallumina S.p.A. was substantially completed. Deliveries of bauxite from Weipa, Australia, began in July 1972, and the first shipments of alumina from the new plant were expected in the first half of 1973. Eurallumina is owned by Alsar S.p.A. (41.67%), Montecatini-Edison (20.83%), Comalco (20%), and Metallgesellschaft A.G. (17.5%).

Jamaica.—Although the bauxite mines and alumina plants in Jamaica were operated below rated capacities in 1972 because of a continued oversupply of aluminum on world markets, alumina production was increased 18%. This increase, when compared with only a slight increase in bauxite production, reflected a trend to process a larger percentage of the bauxite in Jamaica.

Alcoa's new alumina plant in Clarendon Parish came onstream at an annual rated capacity of 550,000 short tons. Alumina Partners of Jamaica, Ltd. (Alpart), owned by Anaconda, Reynolds, and Kaiser, completed the expansion of its alumina plant at Nain, St. Elizabeth Parish, to a capacity of 1.3 million tons.

A national Bauxite Commission was created to insure that Jamaica's large bauxite resources are developed for the maximum benefit to the country.

Japan.—According to the Japanese Light Metal Smelters Association, suppliers' exports of bauxite to Japan increased 16% in 1972 as follows:

Supplier	Quantity (thousand long tons)	
	1971	1972
Australia:		
Comalco Ltd	2,186	2,177
Nabalco Pty. Ltd. (Gove)	78	534
Indonesia: P.N. Aneka Tambang	895	1,089
Malaysia:		
Ramunia Bauxite Co	258	220
Southeast Asia Bauxites, Ltd	451	475
Total	3,868	4,495

Nippon Light Metal Co., Ltd., put into operation its 397,000-short-ton-per-year alumina plant at Tomakomai, Hokkaido. Initial production was delayed until plans for offshore disposal of the red mud from the plant were changed to a disposal site on land. Mitsui Alumina Co. began production at its 220,000-ton-per-year Wakamatsu alumina plant, Kyūshū, using bauxite from Gove, Australia. The capacity of the plant was to be doubled by 1975. Chofu Alumina Co., formed by Mitsui Mining and Smelting Co. Ltd. and Ardeco, a consortium of Japanese primary aluminum producers, postponed until at least 1975 plans for completion of a 550,000-ton-per-year alumina plant to use bauxite from the Solomon Islands (British).

A joint venture, composed of Alcoa (75%) and Morimura Bros., Inc. (25%), was formed to construct facilities by 1974 to produce tabular alumina for use as a refractory material.

Solomon Islands (British).—Mitsui Mining and Smelting Co. of Japan continued the development of bauxite deposits on Rennell Island. Initial shipments to Japan were expected to begin in 1973. Conzinc Riotinto of Australia, Ltd., continued exploration of bauxite deposits on Wagina Island. The Wagina bauxite occurs as a fine-grained clayey material high in moisture. Reserves were expected to total 30 million long tons.

Surinam.—Early in March the Billiton Mine Workers Union struck the Billiton mine for higher wages for the 1,500 workers. The strike had little effect on total production for the year.

Reynolds Metals Co. continued its exploration for bauxite in the Bakhuys Mountains in western Surinam. Until such time as the company can show 50 million tons of commercial grade bauxite, Surinam was not expected to proceed with building the railroad from the deposit to the port of Apoera on the Corantijn River.

Exports of bauxite were down 3% for the year, but exports of alumina were up 9% over the quantity in 1971.

Taiwan.—The Government-owned Taiwan Aluminium Corp. (Talco) imported its bauxite supply from Malaysia and Australia. Talco planned to expand its alumina production capacity to 154,000 short tons by 1975.

Turkey.—Construction of an alumina plant at Seydişehir about 180 miles south of Ankara was expected to be completed in 1973. The plant will have a capacity of 220,000 short tons and will use bauxite from deposts near Akseki in the western Taurus Mountains, where reserves have been estimated at 30 million tons.

Yugoslavia.—An agreement was reported to have been signed between the U.S.S.R. and the Yugoslav enterprise Energoinvest to develop bauxite mines in Bosnia-Hercegovina and to construct a 660,000-ton-capacity alumina plant at Zvornik. The total cost of the venture was estimated at $200 million. The U.S.S.R. will provide $130 million in credit, which will be repaid in alumina and bauxite. Production from the mines, located at Vlasenica, Jajce, and Bosanska Krupa, are to be increased to over 2.5 million tons by 1976.

TECHNOLOGY

Alunite, a hydrous potassium aluminum sulfate mineral, continued to be investigated as a commercial source of alumina in the United States. The only known commercial-size plant is operating in the U.S.S.R., at Sumgait, near the Caucasus mountains. A new process to recover fertilizers and either aluminum salts or alumina from alunite reportedly was developed in Mexico in 1971 and was expected to be used in a small plant to be built at Salamanca.

In this process the potassium in alunite was dissolved for 10 to 15 minutes in a weak basic solution such as aqueous ammonia and recovered for fertilizer use. The residue, containing the alumina, was treated successively with a weak acid and a strong acid, forming a basic aluminum salt and alumina trihydrate, which was filtered and calcined. Aluminum recoveries at a 5-ton-per-day pilot plant reportedly ranged between 90% and 92%.[4]

A joint venture of Earth Sciences, Inc., National Steel Corp., and Southwire Co., continued field investigations of alunite deposits at the southern end of the Wah Wah Mountains in Beaver County, Utah. The companies reportedly controlled indicated and inferred reserves of over 680 million tons of alunite-bearing rock in the area, containing over 40% alunite, equivalent to 100 million tons Al_2O_3, and had interests in other alunite properties in Utah, Colorado, Arizona, and Nevada. The joint venture was investigating a proprietary process to recover alumina and potassium sulfate from alunite, believed to be similar to the process that was under development in Mexico.

Based on present alumina plant capacities, a commercial plant utilizing alunite probably would require a deposit containing 50 million tons of alunite, equivalent to 8 million tons of alumina. Since there has been no domestic commercial use of alunite as a source of alumina, little information on reserves was formerly available.

Anorthosite, an aluminum silicate mineral, also was being considered as a possible alternate source of aluminum. Alcoa purchased an 8,000-acre deposit of anorthosite containing about 28% alumina, in Wyoming and continued to study ways to recover aluminum from such material. The Bureau of Mines released two reports on its investigations of dawsonite, a sodium-aluminum carbonate mineral which occurs in Colorado oil shale deposits and is a potential source of aluminum.[5]

Results of studies of the mineralogy, geochemistry, geology, and genesis of bauxite deposits throughout the world were published.[6]

Nikkei Sangyo, a subsidiary of Nippon Light Metals Co., was starting up the worlds first commercial plant using red mud to produce a substitute for fluorspar in making steel.[7] Red mud is a solid waste generated in producing alumina from bauxite. About 1 ton of red mud is generated for each ton of alumina produced. At most alumina plants red mud is impounded in red mud lakes and represents a loss of space as well as of sodium and aluminum values.

Kaiser Aluminum & Chemical Corp. developed a method for handling red mud from its Baton Rouge and Gramercy alumina plants in Louisiana in lieu of dumping it in the Mississippi River. The mud will be transported by pipeline from the alumina plants to storage areas on company property where it will be poured over a layer of river sand and dewatered. The resulting alkaline solution will be pumped back to the alumina plant and recycled. The dewatered red mud will then be covered with topsoil and planted or removed from the site and used as landfill and for other purposes.

The red mud treatment system at both plants was expected to be completed by mid-1975 and cost in excess of $25 million.[8]

Beryllium

By Robert A. Whitman [1]

The consumption of beryl decreased in 1972. Production of domestic ore declined, and imports were less than those of 1971. Contracts were awarded for beryllium components of the Poseidon missile system to be delivered in 1973 and 1974.

Table 1.—Salient beryllium mineral statistics

[1] Includes some bertrandite ore that was calculated as equivalent to beryl containing 11% BeO.

Legislation and Government Programs.—Government yearend stocks of beryl, beryllium-copper master alloy, and beryllium metal are shown in table 2. Government inventories of beryl decreased 1,602 short tons during 1972 as a result of sales.

The Environmental Protection Agency held public hearings in New York City on January 10, 1972, and in Los Angeles on February 15 and 16, 1972, to obtain testimony concerning emission standards for the three air pollutants, asbestos, beryllium, and mercury. Final emission standards are due to be published in 1973.

DOMESTIC PRODUCTION

Production of beryl ore was believed to be the lowest in several years. Some beryl was produced in Colorado and South Dakota, but most mines reported assessment work only. The largest domestic source of beryllium ore was the Spor Mountain bertrandite mine near Delta, Utah. Production of beryllium-copper alloy increased, but the production of metal declined from that in 1971.

Brush Wellman, Inc. (Brush), converted bertrandite from its Utah mine to beryllium hydroxide at Delta, Utah, and shipped the hydroxide to Elmore, Ohio, for further conversion to metal, alloys, and compounds. Brush also has beryl processing facilities at Elmore.

Kawecki Berylco Industries, Inc., (KBI) used beryl for its primary ore, most of which was imported. The beryl was processed at Hazelton, Pa. Further processing and fabricating was done at both the Hazelton and the Reading, Pa., plants.

CONSUMPTION AND USES

The beryllium industry consumed beryllium ore equivalent to 7,781 short tons of beryl containing 11% BeO. There was less beryllium metal and beryllium oxide ceramics shipped in 1972 than in 1971, but there was a substantial increase in the amount of beryllium-copper master alloy shipped in 1972. Beryllium-copper alloy products consumed the largest quantity of beryllium. These alloys combine the properties of good electrical and thermal conductivity, strength, hardness, and resistance to fatigue, corrosion, and wear. They are used in an ever-increasing variety of electrical and electronic systems. Beryllium-copper also is used increasingly as a tooling material for molding plastics.

Beryllium metal is being used where a high strength-to-weight ratio is needed, as in the aerospace industry. It was used for optical structures in space, for X-ray windows, and in missile parts and nuclear structures.

Beryl Ores, Arvada, Colo., bought beryl ore to process for the ceramics industry.

STOCKS

Consumer stocks of hand-sorted beryl at the end of 1972 totaled 6,913 short tons compared with 6,299 short tons at yearend 1971. Dealers' stocks of beryl are not reported. Stocks of bertrandite are company confidential data.

PRICES AND SPECIFICATIONS

Domestic beryl prices were negotiated between producers and buyers and were not quoted in the trade press. The price of imported beryl probably was negotiated. In February the quoted price range for imported beryl was reduced as a result of the weak market to a range of $30 to $35 per short ton unit from the $35 to $37 range in January. This price range was quoted until yearend.[2]

Prices for beryllium metal products remained steady throughout 1972. Beryllium billet was quoted at $70 per pound, 98% powder prices ranged from $54 to $66 per pound, and 5-inch diameter rod at $102 per pound.

Beryllium-copper master alloy started the year quoted at $54 per pound of contained beryllium and dropped June 1 to $53 per pound, the yearend price. Casting ingot containing 2% to 2.25% beryllium in copper started at $2.10 per pound, dropped on June 1 to $2.06 per pound, and stayed at that level the remainder of the year. The quoted price for Alloy 25 was $3.14 per pound until June 1 and dropped to $3.05 per pound through yearend.

---

[2] Metals Week. V. 43, Nos. 1–52, January-December 1972.

FOREIGN TRADE

Exports of beryllium alloys, waste, and scrap more than doubled, but the total value decreased by 20%.

Imports of beryl decreased for the third consecutive year and were down 17% from 1971. Value per ton was down by 10%. About 84% of the beryl came from Brazil, the Republic of South Africa, and Argentina, with Brazil furnishing over one-half of the imports. In addition to the imports of beryl, there were nearly 12 tons of beryllium products, wrought, unwrought, waste, scrap, and compounds imported with a value of $286, 922.

WORLD REVIEW

Australia.—A new beryl mine was opened near Perenjori, about 200 miles northeast of Perth. Seleka Mining and Investments, Ltd., initiated a drilling program in 1972 to determine the extent of beryl mineralization and was expected to produce beryl for export.

Brazil.—There were reports from the State of Minas Gerais of new beryl reserves to be developed with a Banco Nacional de Desenvolvimento Econômico loan of $15,000.

Japan.—The Japan Society of Newer Metals announced the capacity for production of a little more than 1 short ton annually of beryllium metal by electrolytic refining. The capacity for producing beryllium oxide was nearly 80 short tons per year, mostly by the silicofluoride process. The capacity for producing beryllium copper master alloy was about 800 tons per year. Production figures for 1972 were not available. Japan imports beryl principally from Africa, Brazil, and Australia.

[e] Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, the Territory of South West Africa also may have produced beryl, but mineral production of this area has not been officially reported since 1966, and no reliable information is available as a basis for estimating output since that time. India, listed as a major producer in previous editions of this table (with output estimated in the order of 1,450 short tons annually) has been deleted from the producer list because information now available indicates that little if any beryl mining has been carried out in recent years.

[2] Exports.

TECHNOLOGY

The increasing concern with environmental pollution led to increased research to develop more selective analytical methods. A routine method of analysis for ultratrace concentrations of beryllium in particulate matter collected on air and water filters was described.[3]

A report on the hydrolytic behavior of toxic metals, prepared by the Oak Ridge National Laboratory,[4] should assist in determining methods to remove beryllium from water.

A process for making high strength beryllium by hot-pressing, extruding, and upset-forging, was described.[5] Isotropic compressive yield strengths of greater than 100,000 pounds-per-square-inch were achieved.

A way to bypass the traditional brittleness of beryllium by a technique of diffusion-bonding thin sheets into a laminated plate was reported. The resulting plate had better mechanical properties than the thin sheet from which it was made, and properties substantially superior to sheet rolled directly from ingot to similar thickness.[6]

One paper reported efforts to improve ductility of beryllium by precipitation of about 1% iron from supersaturated solutions of iron in beryllium utilizing the Mössbauer effect.[7]

Further progress in reinforcing a titanium matrix with beryllium to improve rigidity and decrease weight of turbine fans and compressor blades resulted from work on Contract N00019-72-C-0247. This work was performed for the Department of the Navy, Naval Air Systems Command.

The need for substrates with high thermal conductivity for thin film electronic circuitry led to a study of the preparation of BeO by thermal decomposition of the sulfate phase.[8] A Brush scientist reported on the important aspects of heat-treating beryllium-copper alloys. KBI introduced a new alloy they designated Berylco 21C.

Five patents on the leaching of beryllium from its ores were noted, four from the United States and one from Canada.[9] Another U.S. patent dealt with the recovery of beryllium from low-grade ores by reacting the ore directly with anhydrous sulfur trioxide.[10]

The Bureau of Mines continued inhouse research on the casting of beryllium alloys showing promise of ductility, fracture toughness, and weldability. Castings made with a beryllium alloy containing 10% combined nickel and aluminum were very porous and had the appearance of having a high gas content. A proprietary mold from a commercial casting company and a graphite mold coated with beryllium oxide were used. Some porosity seemed to be due to mold reaction. The work was to be continued.

Bismuth

By J. M. Hague [1]

After declining in the preceding 2 years, consumption of bismuth in the United States during 1972 increased about 40% to a level near the annual average of the 1961–70 period.

The price of bismuth was generally firm during the year but at a level substantially below the average of recent years. Sustained demand however, brought a price increase in the fourth quarter. Domestic production increased only slightly and the increased demand was met by increased imports and by sales from the Government stockpile. World production outside the United States increased slightly and reached a new record. World production and consumption of bismuth has grown at a faster rate during the last 30 years than U.S. production and consumption; the centers of production are shifting toward foreign mines and smelters.

Legislation and Government Programs.—The General Services Administration (GSA) continued to sell surplus stocks of bismuth from the national stockpile during the first three quarters of 1972. On October 10, announcement was made that all bismuth remaining in inventory was required in order to meet the stockpile objective at that time, 2.1 million pounds; the sales program was terminated under the authorization of Public Law 91–318 (approved July 10, 1970). Sales during 1972 were 235,100 pounds. The stockpile inventory at the end of the year was 2,204,733 pounds.

Bismuth remained on the list of commodities eligible for exploration assistance from the Office of Minerals Exploration (OME) covering 75% of the cost; but no contracts were in effect during 1972 and no applications were pending.

Federal income tax laws under the Tax Reform Act of 1969 provide a percentage depletion allowance of 22% for domestic production and 14% for U.S. companies producing from foreign sources.

DOMESTIC PRODUCTION

Bismuth produced by domestic smelters or refineries is obtained principally as a byproduct from treatment of domestic and foreign lead concentrates, and from processing leady flue dusts from copper converting processes. The principal producers were American Smelting and Refining Co. (Asarco), Omaha, Neb., and UV Industries (formerly U.S. Smelting Refining & Mining Co.), East Chicago, Ind. UV Industries closed its Tooele, Utah, lead smelter in January 1972, thus shutting off the supply of western bismuth-bearing products formerly refined at the East Chicago plant. Production from UV Industries in 1972 was mostly from inventory material, and its future operations will depend on a supply of secondary lead. A small amount of metallic bismuth, about 1% of domestic production in 1972, was recovered from secondary material by United Refining & Smelting Co. at Franklin Park, Ill.

Domestic refinery production statistics are withheld to avoid disclosing individual company confidential data. Total refinery production at the three plants increased a little more than 1% above the 1971 level. Although domestic production is not revealed in tabulated world production, the U.S. usually ranks among the first six producing countries. The proportion of domestic production that comes from imported concentrates, bullion, and dusts can be estimated only roughly; it is probably no more than half.

Cerro Corp., New York, is the principal U.S.-owned foreign producer and importer. It also owns a substantial domestic consuming subsidiary, Cerro Metal Products Division. Cerro refines in Peru a large part of the bismuth-bearing ores produced from the surrounding Andean region.

CONSUMPTION AND USES

The domestic consumption of bismuth in 1972 recovered from the low usage reported for 1971 to a rate more consistent with long-range trends. Current annual consumption of 2,315,500 pounds is only slightly below the average annual consumption for 1961–70 (2,346,000 pounds).

The pharmaceutical group, including therapeutic agents, cosmetics, and industrial and laboratory chemicals continued to be the largest consuming market for bismuth products. The licensing of new plants to produce acrylic acid using a bismuth catalyst may have revived the consumption of bismuth for catalytic chemicals.

The use of bismuth in fusible alloys increased 47% over 1971 consumption as a result of increased industrial activity and a relatively low price for bismuth during the first three quarters of 1972.

Bismuth used in metallurgical applications, as an alloy to improve machinability of aluminum, steel, and malleable iron, showed a 52% increase, probably due mainly to increased production in the automotive industry.

Table 3.—Bismuth metal consumed in the United States, by use

STOCKS

Stocks of bismuth metal held by domestic consumers decreased during 1972 from 1,107,200 to 717,500 pounds. Sales of Government surplus stocks during the year by GSA amounted to 235,100 pounds. During the last quarter of 1972, sales of bismuth from the Government stockpile were discontinued because the remaining inventory was required to meet the stockpile objective. If the objective is reduced in 1973, the stockpile may again become a domestic source of bismuth.

PRICES

The price of refined bismuth as quoted by the American Metal Market remained at $3.50 per pound until October 1. An increase to $4 per pound was announced as of October 2 by Cerro Corp. and Asarco. The London Metal Exchange price for bismuth in ton lots, c.i.f., as reported by Metal Bulletin of London, was $3.20 per pound in January, $3.60 in April, $3.25 in July, $4 in October, and $4.05 on December 29. The reason given by U.S.-based producers for the price increase in October was that stocks were getting low and production was limited. Producer and dealer prices were firm at the end of the year, and the outlook was for a possible increase in price during 1973.

FOREIGN TRADE

Exports of bismuth metal, alloys, and waste and scrap went to 15 countries for a total shipment of 264,000 pounds. This was more in line with exports in previous years after the surge in 1970. Belgium received 36% of the total, United Kingdom 24%, Canada 14%, and other countries 26%.

Imports of metallic bismuth increased to 1,563,000 pounds, second only to the 1966 record amount, in order to satisfy the increased demand that grew with a relatively static domestic production and a reduced amount sold from the national stockpile. The imports of metallic bismuth were augmented by 233,000 pounds gross weight of bismuth-lead alloys from Mexico and 35,000 pounds gross weight of alloys from Peru. Bismuth compounds and mixtures were imported in the amount of 7,400 pounds from European countries, half from West Germany.

Table 4.—U.S. exports of bismuth [1]

Year	Gross weight (pounds)	Value
1969	447,931	$1,515,368
1970	910,275	2,332,423
1971	71,187	199,084
1972	264,276	492,585

WORLD REVIEW

Market conditions for bismuth improved during 1972 from the oversupply situation in 1971. World production, excluding U.S. production, increased to an estimated record high of 8.8 million pounds. Consumption in the United States increased more markedly than that in the rest of the world. Most bismuth continued to be produced as a byproduct from smelting copper, lead, molybdenum or zinc ores and concentrates and from treatment of smelter residues; however, two new smelting plants have been designed to produce bismuth as a major product, one in Bolivia, now in operation, and one in Australia, scheduled to start in 1973.

Australia.—Mine production in 1972 exceeded 830,000 pounds, produced mainly by Peko-Wallsend Ltd. from the Juno mine near Tennant Creek, Northern Territory. Ore reserves at the Juno mine are given as 170,000 tons assaying 1.95 ounces of gold per ton, 0.8% bismuth, and 0.4% copper. The Peko, Warrego, and Orlando mines of the same company were in production, but not on bismuth-bearing ores. Ore reserves at Peko are 750,000 tons assaying 0.1 ounce of gold per ton, 3.2% copper, and 0.15% bismuth; ore reserves at Warrego are 5,000,000 tons assaying 0.1 ounce of gold per ton, 2.6% copper, and 0.3% bismuth; and ore reserves at Orlando are 100,000 tons assaying 0.035 ounce of gold per ton, 5% copper, and 0.1% bismuth. Peko-Wallsend Metals Ltd., a subsidiary, has made good progress in the construction of a smelter at Tennant Creek designed to produce low-bismuth blister copper and crude-bismuth bullion. The initial operation of the plant was scheduled for March 1973 with a planned capacity of over 2,000,000 pounds of bismuth annually. Current bismuth production is shipped as concentrates to Japan at the rate of about 500,000 pounds of bismuth metal per year. The completion of the Tennant Creek smelter will probably be accompanied by an increase in mine production and will make Australia a major world source of bismuth.

Bolivia.—COMIBOL (Corporación Minera de Bolivia) opened its new bismuth smelter at Telamayu in May 1972. The plant is designed to handle 440 short tons

• Estimate. [p] Preliminary. [r] Revised. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, Brazil, Bulgaria, East Germany, and South-West Africa are believed to produce bismuth, but information is inadequate to make reliable estimates of output levels.

[2] Less than ½ unit.

[3] Production by COMIBOL and exports by medium and small mines.

[4] Exports by all producers.

[5] Bismuth content of refined metal and bullion, plus recoverable content of concentrates exported.

per month of concentrates to produce 150,000 pounds per month of bismuth metal or about 1,800,000 pounds per year. In the past, concentrates have been sent to Peru or Europe for smelting and refining at the rate of about 1,400,000 pounds per year; the new installation, if operated at design capacity, will increase Bolivia's contribution to world production of bismuth metal.

In November, COMIBOL announced that meetings would be held in La Paz with other international bismuth interests to establish lines of communication among producers and to form a Bismuth Institute to investigate new uses, promote growth, and keep statistics on consumption.

Canada.—Bismuth production as a byproduct of molybdenum ores in western Quebec has been curtailed by the closing of several molybdenum mines. However, increased bismuth production from lead concentrates by Cominco, Ltd., at Trail, British Columbia, and by Brunswick Mining and Smelting Corp. Ltd. at Belledune, New Brunswick, partially offset this loss so that the total bismuth production for Canada increased about 50% from the 1971 production level, although it was still below the 1970 output.

Japan.—According to preliminary estimates, Japan led the world in the production of bismuth metal in 1972. Production from its eight metallurgical plants is a byproduct of the treatment of copper, lead, and zinc ores and concentrates. Much of the Japanese production is thought to come from imported concentrates and residues, so its mine production may be only part of the reported output. The rate of production reported for several consecutive months in 1972 was about 165,000 pounds per month.

Mexico.—Most bismuth metal production in Mexico is exported after recovery from impure lead bars or bullion. The two principal producers are Asarco Mexicana, S.A., at its Monterrey refinery and Metalurgica Mexicana Peñoles, S.A., also at Monterrey. Bismuth-bearing lead bullion is also exported to the United States and the United Kingdom for further refining; roughly one-fifth of total Mexican bismuth production is sent to the United States for extraction from bullion by U.S. refiners.

Peru.—Cerro Corp. is one of the principal world suppliers of bismuth from products made by its metallurgical works at La Oroya. A major part of its production is exported and consumed in the United States. Smaller producers in Peru, as well as a few small producers in Bolivia, may ship ore and concentrates to Cerro or export them to foreign refiners.

TECHNOLOGY

A new microfilm process using a thin layer of bismuth on film was announced by Bell Laboratories.[2] A centrifugation process for removing bismuth from lead was developed by the Federal Bureau of Mines.[3] Australian research laboratories developed an electrometallurgical method for debismuthing lead.[4] The thermodynamic, thermoelectric, electrochemical and alloying behavior of bismuth was studied and reported on in several papers.[5]

Boron

By K. P. Wang [1]

Production and domestic consumption of boron minerals continued the rising trend begun in 1961 and reached a new high in 1972. However, recorded exports in terms of B_2O_3 content showed little overall change from 1971 and were considerably lower than the average level in 1969–70. For some time, all U.S. output had been in the form of sodium borates and boric acid. Recently, production of calcium borate (colemanite) on a commercial scale was resumed in California, which provides the entire domestic production of boron minerals.

Legislation and Government Programs.—During 1972 there were no Government programs and no legislation proposed or enacted pertaining to boron. The Government had no stocks, and no procurement programs were in effect.

The depletion allowance remained at 14% for both domestically and foreign-produced borates in accordance with the Tax Reform Act of 1969.

[1] Colemanite only.

DOMESTIC PRODUCTION

Domestic production and sales of boron increased slightly in 1972 compared with those of 1971. Most of the output came from Kern County, Calif., and to a lesser extent from San Bernardino County, Calif.

The large open pit mine of U.S. Borax & Chemical Corp., a subsidiary of the British-owned Rio Tinto Zinc Corp. Ltd., at Boron, Kern County, remained the world's foremost source of boron. U.S. Borax produced upgraded crude sodium borates, refined borates, including anhydrous borax, and boric acid, including anhydrous boric acid, at the mine site. High-purity and specialty products were produced mainly at Wilmington, Calif., and secondarily at Burlington, Iowa. Wilmington was also the company's port of export. These plants headed by the one at Boron had a combined annual capacity of more than 500,000 short tons of equivalent B_2O_3 in 1972. A 3-year, $10 million program to drastically cut down dust emissions at Boron was successfully concluded in 1972.

Kerr-McGee Chemical Corp., formerly American Potash & Chemical Co., and Stauffer Chemical Co. produced boron compounds and other products from brines of Searles Lake in San Bernardino County, Calif., at their almost-adjoining plants in Trona. Kerr-McGee's annual capacity is about 100,000 short tons of B_2O_3 and Stauffer Chemical's capacity 25,000 to 30,000 tons of B_2O_3. In the spring of 1972, Kerr-

---

[1] Physical scientist, Division of Nonmetallic Minerals.

McGee announced plans to build a $100 million soda ash plant along with additional borate refining facilities.

In 1972, Tenneco Oil Co. produced far less colemanite than it had originally planned from its deposit in the Furnace Creek district of Inyo County, Calif., and its nearby processing plant in Nevada. Tenneco had designed the facilities to produce 150,000 short tons of raw colemanite, or roughly 70,000 short tons of calcined colemanite, per year, but actually turned out only a fraction of this, because of difficulties in calcining. The 48% B_2O_3 grade calcined colemanite was shipped primarily to Owens-Corning Fiberglas Corp.'s plants in Anderson, S.C., and Burkette, Tenn.

Although Occidental Petroleum Corp. through its subsidiary Hooker Chemical Corp. was scheduled to become the third borate-producing company on the shores of Searles Lake before yearend 1972, a proposed plant never took shape because of excessive quantities of brines needed.

CONSUMPTION AND USES

U.S. consumption of boron materials is difficult to estimate because of the wide range of products and the large tonnages of exports in the form of both crude and finished borates. Although U.S. Borax is an international company with farflung worldwide interests, it does not disclose details on shipments to foreign countries. Kerr-McGee also exports considerable quantities of borates. Water-borne freight charges from Wilmington, Calif., to Europe are less than those to the east coast United States, because high-cost U.S. bottoms must be used in domestic runs and special low rates are possible on European runs. U.S. Borax's 20,000- to 30,000-deadweight-ton ships carrying borates to Europe often come back with Volkswagens that pay for a large part of the freight charge.

Generally speaking, about one-half of the U.S. output of boron minerals and compounds was consumed at home, and the other one-half was exported. Official U.S. trade statistics do not list crude borates as a separate category and imply that none is exported. Actually, shipments of unfinished products to foreign countries were larger than those of fully refined products.

An estimated 40% to 45% of the boron compounds consumed were used in manufacturing various kinds of glasses within the United States. Boron materials account for 5% to 10% of many special glasses by weight and 50% to 75% by value. About 15% of all boron consumed went into insulating fiber glass, 10% into textile fiber glass, and 15% to 20% into all other glasses. The manufacture of enamels, frits, and glazes for protective and decorative coatings on sinks, stoves, refrigerators, and many other household and industrial appliances accounted for another 10% of the boron consumption.

Approximately 15% of the boron compounds consumed in the United States, (about one-third in the form of sodium perborate detergents), went into soaps and cleansers during 1972. Herein lies one major difference in U.S. and European consumption patterns. In Europe, sodium perborate detergents, used primarily in high-temperature washing, account for more than one-quarter of the boron consumed whereas in the United States, consumption for cleansers is higher. Borax and boric acid are used in the cleansing field because of their bactericidal characteristics, easy solubility in water, and excellent water-softening properties. They also go into toothpaste, mouthwash, and eyewash.

Borax added to fertilizers to supply boron as an essential plant nutrient accounted for about 5% of the U.S. boron demand. Another 2% to 3% went into the making of herbicides. Substituting colemanite for fluorite in steelmaking did not progress beyond the pilot plant stage.

About one-fourth of the boron consumed in the United States went into many miscellaneous uses. Minor amounts of boron compounds were used as fluxing materials in welding, soldering, and metal refining. Some elemental boron was used as a deoxidizer in nonferrous metallurgy, as a grain refiner in aluminum, as a thermal neutron absorber in atomic reactors, in delayed action fuses, as an ignitor in radio tubes, and as a coating material in solar batteries. Use of boron compounds in abrasives gained ground, particularly cubic boron nitride produced by synthetic diamond producers. Use of boric acid as a catalyst in the air oxidation of hydrocarbons accounted for more than 3% of the boron consumption. Boron materials went into many other areas, including direct consumption in chemicals, conditioning agents or precursors to chemicals, plasticizers, adhesive additives for latex paints, fire retardents, antifreeze, textile and paper products, biocides in jet fuels, photography, and composite materials.

PRICES

Prices of virtually all borate products at yearend 1972 were the same as the prices posted for yearend 1971. Elemental boron prices were quoted at yearend 1972 by the American Metal Market as follows, per pound, in ton lots: 90% to 92% $13; 97% to 99% $18; and over 99%, $70. Prices of various boron compounds are shown in table 2.

Table 2.—Prices of boron compounds at yearend, 1972

FOREIGN TRADE

U.S. exports of boric acid were 27,655 short tons (valued at $4.2 million) in 1972, compared with 36,409 tons in 1971. Exports of refined sodium borate showed little change—162,123 tons (valued at $18.3 million) in 1972 and 166,087 tons in 1971. The overall level of exports of all the refined boron compounds was therefore about the same during the last 2 years and considerably below the average level during 1969–70. As noted, these figures hardly tell the whole story since exports of crude borates were actually higher than exports of refined borates.

Detailed breakdown of the recorded exports in 1972, namely boric acid and refined sodium borate, are shown in table 3. Within this table, data for all countries outside Western Europe are accurate. The problem for Western Europe is that the Netherlands distorts the total because this country is primarily a transshipment point for boron compounds to other nearby countries. A more meaningful estimate embracing crude borates as well would show that West Germany, the United Kingdom, France, and Japan were the ranking final export destinations, in that order, and the Netherlands was actually eighth in 1972.

In 1972, the United States imported 20,227 short tons of calcium borate (colemanite) valued at $626,000, all from Turkey. This tonnage was of nearly the same magnitude as the average imports during 1968–70 and approximately three times the 1971 imports.

WORLD REVIEW

Argentina.—Argentina's output of sodium borates has increased from about 23,000 short tons in 1968 to more than 50,000 tons in 1972, but overall potential is far from extensive. Ores mined in the Andes are trucked from Tincalaya to Quijano in the lowlands for processing. The principal producer, Boroquimica Limitada, is another subsidiary of Rio Tinto Zinc Corp. During 1970–71, recorded exports of processed borates from Argentina were about 12,000 tons per year, mainly to Brazil.

China, Peoples Republic of.—Large resources of borates are claimed by the Chinese, particularly for the Iksaydam dried lake area of Tsinghai Province. The textile fiber glass industry in China, which consumes considerable borates, has been expanded sharply in recent years. For some time now, China has shipped a few thousand tons of surplus borates annually to Japan.

Turkey.—Turkey's 1972 output of boron minerals registered another increase over the 629,000 short tons of 39% B_2O_3 grade crude product reported for 1971. Virtually all of this was colemanite, as the extensive deposits of sodium borates have not yet been developed. The output was shipped mainly in the crude form to refineries in Europe. Approximately one-half of Turkey's 1970–72 colemanite production was accounted for by the Government-owned Etibank, which announced the completion of a 600,000-ton concentrator in the Kirka area in mid-1972.

The nationalization issue was not yet resolved by yearend so that the three existing private producers of borates headed by

Rio Tinto Zinc Corp.'s subsidiary Türk Boraks Madençilik Co. were still operating independently. A new coalition government under Feret Melen, in power since the spring of 1972, has introduced a bill in parliament concerning nationalization which was still pending at yearend. With a 50–50 chance of passage, the bill stipulates that boron would be one of four major mineral industries to be nationalized and private owners would be compensated according to "book value."

TECHNOLOGY

Use of colemanite as a substitute for fluorspar in the basic oxygen furnace steel process did not make any headway beyond the testing stage.

In the field of cement manufacture, it was claimed that the addition of 1.5% to 2.5% by weight of boron trioxide in the form of boric acid, calcium tetraborate, or crude colemanite to the raw mix results in a more easily grindable clinker and ultimately a stronger cement.

Boron was being investigated by the U.S. Air Force as part of a fluidized-solids propellant mixture to be used in aerospace rockets.[2] The propellant would consist mainly of fluidizing gas with solids representing only about 1% of the weight.

Use of boron and titanium in grain refining of aluminum and its alloys was discussed.[3]

Less expensive ways for producing boron nitride for abrasives were being investigated.

Bromine

By Charles L. Klingman [1]

The bromine industry displayed surprising vitality in 1972. In spite of efforts to reduce atmospheric pollution from automobile exhausts, the predicted reduction in use of tetraethyl lead as an antiknock and ethylene dibromide as a lead scavenger in gasoline did not occur. There was, in fact, an increase of more than 13% in ethylene dibromide production in the United States, compared with that of 1971. The increase was caused, to some extent, by increased exports of antiknock compounds, which include ethylene dibromide particularly to the United Kingdom and Brazil.[2] In 1972 total bromine production increased by 30,918,000 pounds over 1971 production. It is probable, however, that the large 1972 gain will not be maintained in 1973 and subsequent years.

DOMESTIC PRODUCTION

The State of Arkansas continued to gain in bromine production, with 1972 output about 17% above that of 1971. Michigan had a 6.6% reduction in output. The high bromine concentration and large reserves of Arkansas underground brine makes this State a logical location for future expansion. The brine wells of Michigan, by comparison, were not as free-flowing and had lower bromine content. Therefore, more wells had to be drilled and more brine had to be handled in Michigan per pound of bromine produced.

About 10% of the total bromine produced was sold in the elemental state to nonmanufacturers of bromine compounds. The fraction of the bromine production not used in the manufacture of compounds had remained relatively constant over the years.

The rate of bromine production in 1972 was 9% higher than that of 1971. The historic growth rate for the industry was about 7% per annum.

Table 1 presents data only on elemental bromine. The bromine classified as "used" in table 1 is the same bromine that appears in table 2 as the "bromine content" of manufactured compounds, except for processing losses and variations in stocks on hand. Table 2 deals exclusively with bromine compounds manufactured for the end use market.

In 1972 there were 10 bromine producing plants in three States operated by

	Morton Chemical Co.	Manistee	Manistee	Do.

seven companies. Two of these plants extracted elemental bromine only for sale and did not produce compounds. In addition, other plants, not shown in table 3, made compounds only from purchased bromine.

CONSUMPTION AND USES

The Bureau of Mines has not surveyed the consumers of bromine and bromine compounds for many years and therefore does not have 1972 data on the final disposition of these products. It was known, however, that over 74% of U.S. production in 1972 went to the manufacture of ethylene dibromide. Most of this production was used in gasoline additives, but the compound was also used in agriculture and as a solvent. In 1971 there was great pessimism over the future of ethylene dibromide because of the Clean Air Act of 1970, which required a 90% reduction in harmful emissions from automobile exhausts by the year 1975. This pessimism, however, was apparently not justified by actual conditions because, in 1972, the industry rebuilt depleted inventories and developed new markets for bromine compounds.

The use of bromine in the manufacture of flame retardants was also believed to be on the increase. It was estimated that between 3% and 4% of total bromine production went into the manufacture of flame retardants in 1972.

Agricultural chemicals also increased, but the extent of the increase was not known. Methyl bromide was classed primarily as an agricultural chemical because of its extended use as a soil sterilant and insect fumigant. Many of the agricultural chemicals were proprietary, and their exact composition was not widely known.

Elemental bromine was utilized as a disinfectant, algaecide, and as an oxidizing intermediate in the manufacture of other chemicals.

PRICES

Prices quoted at yearend for bromine and bromine compounds in Chemical Marketing Reporter were as follows:

	Cents per pound
Bromine, purified:	
Cases, carlots, truckloads, delivered east of Rocky Mountains	49
Zone I: [1]	
Returnable drums, carlots, truckloads, delivered	30
Bulk tank car, tanktrucks (45,000-pound minimum), delivered	17
Ammonium bromide, national formulary (N.F.), granular drums, carlots, truckload, freight equalized	48.5
Bromochloromethane, drums, carlots, freight equalized	54.5
Tanks, same basis	53
Ethyl bromide, technical, 98% drums, carlots, freight allowed, East	68
Ethylene dibromide, drums, carlots, freight equalized	25
Tanks, freight equalized	20
Methyl bromide, distilled, tanks, 140,000-pound minimum, freight allowed	34
Potassium bromate, granular, powdered, 200-pound drums, carlots, freight allowed	64–77
Potassium bromide, N.F., granular, drums, carlots	43.5
Sodium bromide, N.F., granular, 400-pound drums, freight equalized	40

[1] Delivered prices for drums and bulk shipped west of Rockies, 1 cent per pound higher. Bulk tanktruck prices 1 cent per pound higher for 30,000-pound minimum and 2 cents per pound higher for 15,000-pound minimum. Price f.o.b. Midland and Ludington, Mich., freight equalized, 1 cent per pound lower.

The average unit price of bromine made by manufacturers in 1972 was about 5% lower than the 1971 price.

FOREIGN TRADE

Exports of bromine and bromine compounds from the United States were not separately tabulated. Scattered reports in the press indicated that bromine exports increased in 1972, but few quantitative data were given.

There was only slight incentive to import any bromine or bromine compounds into the United States in competition with the vast domestic supply and competitive price situation. The actual import figures for 1972 consisted mostly of potassium bromide from France and the United Kingdom. Its total valuation was under $14,000.

WORLD REVIEW

The United States produced and consumed three-fourths of the world production of bromine in 1972.

Israel.—Israel has an enormous resource of bromine estimated at 1 billion tons, in the brine of the Dead Sea. This is a virtually inexhaustible supply when compared to the 1972 production of 30 million pounds of bromine. About one-third of this bromine was converted into compounds within the country, and over one-half of it was exported as elemental bromine to European countries. Elemental bromine was exported in lead-lined steel tanks that held 3.5 tons of bromine each.

Italy.—The bromine industry of Italy was reported to be producing about 6 million pounds of bromine per year. A bromine plant of Margherita di Savoia Apulia, enlarged its production capacity. This plant extracted bromine from local saltbeds.

Japan.—Japan obtained more than 95% of its bromine from sea water and was reported to have produced about 27 million pounds in 1972. One company, Toyo Soda, produced more than 90% of the bromine in Japan and it recently increased its production capacity by 6.6 million pounds per year. Bromine exports from Japan were small, and total imports, mostly from the United States and from Israel were less than 5% of the Japanese consumption.

TECHNOLOGY

The mechanism by which brominated flame retardants and fire extinguishers operate was explained clearly in a recent article by Walter M. Haessler of Florida

State Fire College.[3] A bromide chemical such as bromotrifluoromethane, CF_3Br, interrupts the flame-combustion chain reaction in a dramatic fashion without removal of fuel or air. Under the heat of the flame, CF_3Br is partially ionized and the resultant bromine ion combines with a hydrogen ion of the flame to form hydrobromic acid. This compound, in turn, reacts with a hydroxyl ion of the flame to form water and leaves a bromine ion ready for recycling through the same series. A single bromide ion may thus remove several of the combustion-chain-carrier ions, namely the hydrogen, H^+, and the hydroxyl, OH^- ions. Other bromine-bearing chemicals react in a similar manner.

---

Cadmium

By Burton E. Ashley [1]

Strengthening interest in cadmium was presaged by rising producers' prices that increased from $1.50 early in the year, to $3.00 per pound at yearend. Domestic production of cadmium metal, at 8.3 million pounds, gained 5% over the 1971 level, and value of producer shipments increased by 93% to $19 million. Apparent consumption rose 16% to 12.6 million pounds. Seven companies operating eight plants accounted for all domestic output.

Export trade in cadmium increased considerably from the 1971 quantity of 66,000 pounds to slightly over 1 million pounds; imports for the year declined by 31% to 2.4 million pounds.

Legislation and Government Programs.—Sales from the national stockpile amounted to 959,100 pounds; such sales were authorized by Public Law 91–314 of July 10, 1970. At yearend a total of 9,213,358 pounds of cadmium remained in the stockpile, of which 3,213,358 pounds was available for disposal. The stockpile objective remained at 6.0 million pounds.

On January 10, General Services Administration (GSA) announced that 600,000 pounds of cadmium ingot and slab would be available for sale at $1.58 per pound, f.o.b. storage location, in lots of 2,000 pounds or more, and at $1.63 per pound in lots of less than 2,000 pounds. Sticks in lots of more, or less, than 2,000 pounds were priced at $1.70 and $1.75 per pound, respectively. This offering was disposed of by February 1.

On April 3 an additional 600,000 pounds was put on sale; sticks were priced at $2.55 per pound in lots of 2,000 pounds or more and at $2.60 per pound in lots of less than 2,000 pounds. Slabs and ingots brought $2.43 per pound in lots of less than 2,000 pounds. Disposals in the second quarter amounted to 260,100 pounds. On July 6, GSA announced the availability from the stockpile of 600,000 pounds of cadmium in stick form at $2.55 per pound in lots of 2,000 pounds or more and at $2.60 per pound in lots of less than 2,000 pounds. No cadmium was sold at this offering. For the last quarter of the year cadmium sticks from the stockpile were priced at $2.95 and $3.00 per pound in quantities of 2,000 pounds and more and for lots of less than 2,000 pounds, respectively. Disposals amounted to 99,000 pounds, of which 10,000 pounds was bartered.

At midyear the U.S. Department of the Treasury announced that cadmium from Japan had been imported at less than fair value and that an industry had been injured. As a consequence, special dumping duties were to be assessed on the subject merchandise imported at less than fair value after March 24, 1971. Duties were to be assessed on a case-by-case basis and any sales made at fair value would not be subject to dumping duties.

The Office of Minerals Exploration, U.S. Geological Survey, provides up to 50% of allowable costs of exploration for cadmium to eligible participants. Cadmium producers were granted a depletion allowance of 22% on domestic production and 14% on foreign production.

DOMESTIC PRODUCTION

Domestic production of cadmium metal was fairly uniform at slightly more than 2 million pounds for each quarter of the year, except for the third quarter when output was 1.9 million pounds. Total production for 1972, at 8.3 million pounds, gained 5% over the 1971 level. Value of producer shipments increased over the 1971 total by 93% to $19 million.

---

[1] Physical scientist, Division of Nonferrous Metals.

Imports of flue dust from Mexico contained 741,000 pounds of cadmium for domestic recovery and refining. Other sources of cadmium for U.S. producers were provided by imports of zinc ore and small amounts of waste and scrap.

The cadmium content of sulfide compounds produced (including cadmium sulfoselenide and lithopone) gained 21% over the 1971 level, to 2.7 million pounds.

Cadmium oxide was produced by American Smelting and Refining Company and Blackwell Zinc Co.

Table 1 shows comparative salient statistics for cadmium for 1968–72; table 2 refers to cadmium sulfide output for the same period.

1970	2,137
1971	2,235
1972	2,714

[1] Cadmium oxide withheld to avoid disclosing individual company confidential data.

[2] Includes cadmium lithopone and cadmium sulfoselenide.

CONSUMPTION AND USES

Apparent consumption of cadmium (see table 3) amounted to 12.6 million pounds, a 16% gain over apparent consumption in 1971. Government sales increased considerably from 1,000 pounds in 1971 to 959,100 pounds in 1972.

The plating industry probably accounted for not less than one-half of cadmium consumption in the United States. Cadmium plating affords an attractive thin finish and under marine conditions is particularly resistant to corrosion. Its plating uses included parts for vehicles and boats, small household appliances, hardware, and fasteners, such as nuts, bolts, screws, and other accessories.

Cadmium compounds were used as colorants in plastics, paint, and printing ink; they were also used as stabilizing agents in the manufacture of plastics.

Cadmium was also used as a component of sealed and vented batteries. Such batteries were used to power hand tools and communication equipment, and as independent power sources for internal operational needs in vehicles. Cadmium was used as an alloy for hardening copper, in fusible alloys, and in electrical contacts in switches and relays.

STOCKS

Yearend 1972 industry stocks of cadmium metal and cadmium content of compounds held in stocks totaled 3.3 million pounds, a decline of 37% from stocks held at yearend 1971. Table 4 lists the details of industry stocks as of December 31, 1971, and December 31, 1972.

Table 4.—Industry stocks, December 31

(Thousand pounds)

	1971		1972	
	Cadmium metal	Cadmium in compounds	Cadmium metal	Cadmium in compounds
Metal producers	3,502	W	1,663	W
Compound manufacturers	492	935	451	932
Distributors	r 303	40	228	38
Total	r 4,297	975	2,342	970

r Revised. W Withheld to avoid disclosing individual company confidential data; included with "Compound manufacturers."

PRICES

The cadmium price of $1.50 per pound in 1-ton lots held for the first 2 days of 1972 when it was raised to $1.75 per pound on January 3. There were three more price rises during the year, as shown in table 5. Price for the year averaged out at $2.56 per pound. Trade sources indicated that toward yearend cadmium was being traded at $2.85 to $2.95 per pound. In December the situation changed because balls were in short supply; it was then reported that sticks were trading at $2.95 per pound and balls had advanced to the premium position of $3.15 per pound.

Table 5.—Cadmium prices 1972

(Dollars per pound)

Date	Producer to consumer	
	1-ton lots	Less than 1-ton lots
Jan. 1	1.50	1.55
Jan. 3 to Jan. 31	1.75	1.80
Feb. 1 to Mar. 8	2.25	2.30
Mar. 9 to Oct. 31	2.60	2.65
Nov. 1 to Dec. 31	3.00	3.05

FOREIGN TRADE

Exports of cadmium metal increased from 66,000 pounds in 1971 to over 1 million pounds in 1972. Chief destinations for 1972 exports were as follows, in percent: Netherlands, 30; Germany, West, 21; France, 21; United Kingdom, 16; and others, 12.

The preponderance of exports to the Netherlands was accounted for by shipments consigned to Rotterdam; most of the cadmium thus shipped was forwarded to other destinations which would not be listed in the U.S. statistics.

Imports of cadmium metal, waste and scrap, totaled 2.4 million pounds, a decline of 31% from the 1971 level; the imports of cadmium-containing flue dust, all from Mexico, also registered a substantial decline of 33%. Canada was the chief source of cadmium metal having furnished 44% of total imports, followed by Australia, 17%; Peru, 12%; and Belgium-Luxembourg, 9%. The remaining 18% came from nine different countries. Value of metal imports declined 22% and that of flue dust 39%.

The duty on imported cadmium metal from countries enjoying most-favored-nation status was discontinued in 1971. Cadmium metal imported from Communist-bloc countries, Yugoslavia excepted, was subject to the statutory duty of 15 cents per pound. Imported cadmium-containing flue dust was duty free.

Table 6 shows U.S. exports of cadmium for 1971 and 1972. U.S. imports of cadmium, by country, are shown in table 7.

Grand total	4,611	7,382	3,163	5,571

[1] In 1971 general imports were 3,470,323 pounds ($6,208,146); 1972 general imports and imports for consumption were the same.

[2] Less than ½ unit.

WORLD REVIEW

World smelter production of cadmium increased by 7% over the preceding year to a total of 36,599,000 pounds. The United States held its place as the world's largest producer with 23% of the total; Japan followed with 18%; U.S.S.R., 15%; Belgium, 7%; Germany, West, 6%, and Canada, 5%. The remaining 26% was produced by 22 other countries.

Apparent consumption in the United States was equivalent to about 35% of world production. Table 8 shows preliminary figures of world cadmium production in 1972, by country.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Table gives unwrought metal production from ores, concentrates, flue dusts and other materials of both domestic and imported origin. Sources generally do not indicate if secondary metal (recovery from scrap) is included or not; where known, this has been indicated by footnote. Data derived in part from World Metal Statistics (published by World Bureau of Metal Statistics, London) and from Metal Statistics (published by Metallgesellschaft Aktiengesellschaft, Frankfurt am Main). Cadmium is produced in ores, concentrates and flue dusts in a number of other countries, but these materials are exported for treatment elsewhere to recover cadmium metal, therefore output is not recorded in this table to avoid double counting.

[2] Includes secondary.

[3] Output of Tsumeb Corp. Ltd. for year ending June 30 of that stated.

TECHNOLOGY

An instrument was developed by Pye Unicam of Cambridge, England, which could detect 1 part of cadmium (and lead and zinc) in 1 billion parts of liquid in 20 seconds. It can be used to measure levels of the three metals in the bloodstream.[2]

Yuasa Battery Co., Ltd., of Japan reportedly developed an automatic system for removing harmful heavy metal from industrial effluent; the system will reduce cadmium content in effluents to less than 0.1 part per million. A thin synthetic resin membrane is used as the filtration element. Capacity of the various models ranges from 260 to 7,900 gallons per hour.[3]

A simple electrochemical method of preparing cadmium telluride was described; such compounds are useful for windows in infrared lasers, infrared modulators and as nuclear radiation detectors.[4]

U.S. Patent 3,699,207 was granted for a wet metallurgical process for resin extraction of cadmium from flue dusts or zinc liquor cementates.

Environmental Developments.—The Marine Protection Research and Sanctuaries Act of 1972 (P.L. 92-532) was signed into law in October. The law bans the dumping of certain hazardous materials into the ocean and subjects other materials to regulation through a new permit system. The following month 91 nations reached an agreement which regulates controls for the ocean dumping of toxic and dangerous wastes. As a toxic material, cadmium is one of the metals included in the disposal ban.

[2] Mining Journal (London). V. 278, No. 7123, Feb. 25, 1972, p. 159.

[3] News from Ionics. Ionics Inc., Press release, June 1972, 1 p.

[4] Miles, M. H., and W. S. McEwan. Electrochemical Preparation of Cadmium and Mercury Tellurides. J. Electrochem. Soc., v. 119, No. 9, September 1972, pp. 1188–1190.

The relationship between cadmium pollution and human health received continuing attention. A materials balance was published showing the societal flow of cadmium in the United States for 1968.[5] The flowsheet illustrated the movement of cadmium from mine to environment. Studies have revealed that the daily average human intake of cadmium in the United States is between 0.02 and 0.1 part per million. There was some evidence that a continuous intake of 0.1 part per million may reduce the life span.

Zinc is an essential nutrient for man, but its mineralogical association with cadmium constitutes a hazard to good health. An abstract concerning the relationship of the two metals was published.[6]

The cadmium contamination of soils at a site in British Columbia was evaluated from a standpoint of possible accumulation in man.[7]

H.R. 12958 was introduced to amend the Federal Food, Drug, and Cosmetic Act in February. The Act would regulate the amounts of lead and cadmium which may be released from glazed ceramic or enamel dinnerware. Shortly before H.R. 12958 was introduced it was found that about 100,000 soup bowls had been distributed which contained traces of lead and cadmium. It was thought that the use of the bowls would create no hazard under ordinary circumstances but if they were used to store acid-producing foods, lead and cadmium salts could be released in harmful quantities.

A study of cadmium-related fatal accidents led to determination of quantitative values for cadmium in air. The lethal amount for man of thermally generated cadmium fumes is not over 2,900 minute-milligrams per cubic meter, or an average concentration of 50 milligrams of cadmium per cubic meter of air during a period of 1 hour. Ingestion of 30 milligrams of soluble cadmium salts produced severe toxic symptoms.[8]

Representatives of the Masters Electro-Plating Association (MEPA) in New York presented the city Environmental Protection Administrator with an agreement to remove toxic metals (including cadmium) from waste discharged into surrounding waters. Some 200 electroplating firms were involved. Cost of the collective program was estimated at about $10 million with individual costs reaching as much as $350,000. Equipment will be installed to bring discharges into compliance with the city's sewer regulations.[9]

Calcium and Calcium Compounds

By Avery H. Reed[1]

Calcium metal was manufactured by one company in Connecticut. Calcium-magnesium chloride was produced by two companies in California and three companies in Michigan. Synthetic calcium-magnesium chloride was manufactured by three companies, in New York, Ohio, and Washington.

DOMESTIC PRODUCTION

Pfizer, Inc., produced calcium metal at Canaan, Conn., by the Pidgeon process, in which quicklime and aluminum powder are heated in vacuum retorts. At a temperature of 1170° C, calcium vaporizes and is collected at one end of the retort.

Leslie Salt Co. and National Chloride Co. of America produced calcium-magnesium chloride from dry lake beds in San Bernardino County, Calif. Output declined 32%.

The Dow Chemical Co., Michigan Chemical Corp., and Wilkinson Chemical Corp. recovered calcium-magnesium chloride from wells in Gratiot, Lapeer, Mason, and Midland Counties, Mich. Output decreased 3%.

Total production of natural calcium-magnesium chloride was 4% less than that of 1971 and was 9% below the 1969 record high.

Allied Chemical Corp., Syracuse, N.Y., PPG Industries, Inc., Barberton, Ohio, and Reichold Chemicals, Inc., Tacoma, Wash., manufactured synthetic calcium-magnesium chloride as a byproduct of soda ash. Total output decreased 2% below the 1968 record.

CONSUMPTION AND USES

Calcium metal was used as a reducing agent to separate metals such as columbium, tantalum, thorium, titanium, uranium, vanadium and zirconium from their oxides; to form alloys with aluminum, lead, lithium, magnesium, and silicon; as a scavenger in the steel industry; and in the manufacture of calcium hydride.

The principal use for calcium-magnesium chloride was to melt snow and ice from roads, streets, bridges, and pavements. It was also used to keep down dust on roads and driveways and as an accelerator for concrete.

PRICES AND SPECIFICATIONS

Prices for calcium metal ranged from $1 to $5 per pound. Calcium chloride is usually sold either as solid flake or pellet averaging about 75% $CaCl_2$ or as a concentrated liquid averaging about 40% $CaCl_2$.

FOREIGN TRADE

Exports of calcium chloride, mainly to Canada, Mexico, the United Kingdom, Venezuela, and Sweden, were 18,750 tons valued at $868,400. Exports of dicalcium phosphate, mainly to Mexico, Canada, Brazil, Taiwan, and Thailand, were 19,710 tons valued at $3,277,000. Exports of precipitated calcium carbonate, mainly to Mexico, Canada, Venezuela, South Vietnam, and Honduras, were 8,940 tons valued at $823,000.

Total imports of calcium and calcium compounds were 137,200 tons valued at $7,291,000. Imports of calcium metal from Ontario were 124 tons valued at $181,400. Imports of calcium chloride, mainly from Canada and Belgium, were 6,128 tons valued at $225,500, a decrease of 53% from those of 1971. Imports of other calcium compounds, mainly from Norway, Turkey, Belgium, France, and Canada, were 131,000 tons valued at $6,884,000.

Imports of other calcium compounds included 46,810 tons of calcium nitrate from Norway, Trinidad, Sweden, and West Germany; 20,780 tons of whiting from France, the United Kingdom, Switzerland, and Belgium; 20,230 tons of calcium borate from Turkey; 19,580 tons of dicalcium phosphate from Belgium, Canada, West Germany, and Japan; 11,110 tons of calcium carbide from Canada; 3,165 tons of calcium cyanamide from Canada, Norway, West Germany, and Belgium; 2,467 tons of calcium cyanide from Canada and Japan; 1,895 tons of precipitated calcium carbonate from United Kingdom, Japan, and West Germany; 999 tons of calcium hypochlorite from Japan; 327 tons of chlorinated lime from the United Kingdom and West Germany; and 3,637 tons of miscellaneous calcium compounds.

Table 2.—U.S. imports for consumption of calcium and calcium chloride

Year	Calcium		Calcium chloride	
	Pounds	Value	Short tons	Value
1968	137,251	$120,416	14,069	$522,680
1969	662,200	619,000	9,226	349,998
1970	164,769	141,125	8,280	359,096
1971	48,391	29,751	13,019	543,656
1972	248,080	181,437	6,128	225,463

Table 3.—U.S. imports for consumption of calcium chloride in 1972, by country

Country	Short tons	Value

Total	6,128	225,463

WORLD REVIEW

Canada.—Chromasco Corp. Ltd., produced calcium metal at its Haley, Ontario, smelter. Canada continued to lead all other countries in the production of calcium metal; output in 1971 was 304,000 pounds valued at $282,000. Canada was the leading source of U.S. imports of calcium chloride.

France.—Planet-Wattohm S.A., a subsidiary of Compagnie de Mokta, produced calcium metal by the Pidgeon process.

Carbon Black

By Richard F. Zaffarano [1] and S. O. Wood, Jr.[2]

Carbon black shipments continued their long-term growth pattern in 1972 by increasing 8.0%, following a 6.1% rise in 1971.

Production was a record 3,201 million pounds. Exports continued their decline to a low level of 111 million pounds. A 10.3% gain in domestic sales was one factor that resulted in yearend producer's stocks being 58 million pounds below the 1971 level. The rubber industry continued to be the leading user of carbon black. In 1972, U.S. passenger tire production increased 4% to 195.3 million tires, according to preliminary figures of the Rubber Manufacturers Association, Inc.

The carbon black industry operated at 76.6% capacity in 1972. Daily plant capacity increased 7.2% to a record 11.4 million pounds per day.

Overall production of carbon black in 1972 topped that of the preceding year by 184 million pounds. Channel-black output dropped 24 million pounds.

As shown in table 1, the average value of carbon black at the plant in 1972 was 7.76 cents per pound, an increase of 0.07 cents per pound over that of the previous year.

The volume of natural gas used for manufacturing carbon black declined 9.8 billion cubic feet. Yield also declined from 5.06 pounds per thousand cubic feet in 1971 to 5.02 pounds per thousand cubic feet in 1972. Liquid hydrocarbons feedstocks increased 43 million gallons to a total of 591 million gallons. Average yield increased slightly from 4.92 to 4.96 pounds per gallon.

PRODUCTION AND CAPACITY

Production by State.—Production of carbon black totaled 3,201 million pounds in 1972, an increase of 184 million pounds, 6.1% above the previous year's total. Louisiana supplied 33.7% of the total. Texas' share of the national total was 44.5%. The seven States that produced the remaining 21.8% of carbon black were Alabama, Arkansas, California, Kansas, Ohio, Oklahoma, and West Virginia.

Production by Grade and Type.—Although carbon black was produced by both the channel and furnace processes, the latter accounted for 99.3% of 1972 production. There are seven major grades of carbon black plus thermal black produced by the furnace process. Two of these grades, SRF (Semireinforcing-furnace) and HMF (High-modulus furnace), are gas furnace blacks. The remaining five grades are oil furnace blacks. The HAF (High-abrasion furnace) and ISAF (Intermediate-abrasion furnace) grades continued to lead in the production of oil furnace blacks.

Number and Capacity of Plants.—The total number of producing carbon black plants was 34, three less than in the previous year. In terms of capacity, however, there was an increase from 10.6 million to 11.4 million pounds per day. As shown in table 4, plants in Texas and Louisiana accounted for the major share of the increase in daily capacity.

J. M. Huber Corp. started construction to double its thermal black production capacity to 50 million pounds per year at Borger, Tex.

Materials Used and Yields.—In 1972, a total of 590.8 million gallons of liquid hydrocarbons was consumed in the manufacture of 2,930 million pounds of carbon black. This quantity was 43.1 million gallons more than was consumed in 1971. Yields from liquid hydrocarbons in 1972 averaged 4.96 pounds per gallon, compared with 4.92 pounds in 1971. The yield from natural gas dropped to 5.02 pounds from 5.06 pounds per thousand cubic feet. Natural gas feedstock continued to decrease to 53.9 billion cubic feet, and production from natural gas declined to 271 million pounds, 51.5 million pounds below the 1971 level.

---

[1] Physical scientist, Division of Fossil Fuels.

[2] Petroleum engineer, Division of Fossil Fuels.

CONSUMPTION AND USES

Domestic sales of carbon black increased 10.3% to 3,147 million pounds. Rubber industry consumption increased 10.3% to 2,954 million pounds and accounted for 93.9% of the U.S. total. Sales for use in the manufacture of ink increased 9.7% to 82.5 million pounds. The oil-furnace-type carbon black, known as "Short Ink," was used in manufacturing ink for printing newspapers. Carbon black produced by the channel process, known as "Long Ink," was used in lithographic or halftone printing ink. Consumption of carbon black in paint manufacturing had the greatest increase, 14.5%. The volume of carbon black used in paints increased to 21.4 million pounds. Miscellaneous uses, including chemical, food, and plastics, increased 9.1% to 84.8 million pounds.

STOCKS

Inventory of carbon black at yearend 1972 was 238 million pounds, 19.7% less than comparable yearend stocks in 1971. Largest contributor to the decline was thermal black inventories, which declined from 68 million to 17 million pounds. HAF and SAF were the only grades of furnace blacks that had significantly higher yearend 1972 stocks than at yearend 1971. Respectively, these stocks were 14.6 million and 1.0 million pounds higher. Inventory of channel black at yearend 1972 was 7.7 million pounds, 2.0 million pounds less than yearend 1971 stocks.

FOREIGN TRADE

Carbon black exports totaled 111.3 million pounds, a decrease of 51.9 million pounds from the 1971 total. Value of exports totaled $14.9 million, $5.5 million less than the value of 1971 exports. Furnace black accounted for 89% of exports.

Leading recipients of carbon black produced in the United States were Canada, 19.7 million pounds; Netherlands, 16.0 million pounds; France, 13.8 million pounds; and Japan, 8.0 million pounds. These four countries accounted for approximately one-half of U.S. exports.

Most carbon black imported into the United States was specialty grades. Total imported volume was 7.24 million pounds, of which 6.02 million pounds was acetylene black. Major suppliers of acetylene black to the U.S. were Canada, 5.72 million pounds, and East Germany, 0.25 million pounds. Brazil exported 66,138 pounds of bone black to the U.S. Other major exporters of carbon black to the U.S. included West Germany, 0.58 million pounds, and Indonesia, 0.52 million pounds.

WORLD REVIEW

Carbon black production continued to increase worldwide. Decreased production was not reported for any country. Total world output was estimated to be 7.07 billion pounds. Insufficient data were available to make reliable estimates of output for several countries. (See table 11.) Japan, with an increase of 10.6%, had a high rate of growth. However, the United States, with an increase in output of 184 million pounds, had the largest volume increase.

Worldwide, several new operations and expansions were under construction or in the engineering stage to increase output of carbon black. Among the projects were the following: Cancarb Ltd. was in the engineering stage for a 480-ton-per-day thermal carbon black plant at Medicine Hat, Alberta, Canada. Gofi-Nasr Petroleum Co. had a 10,000-ton-per-year plant at Alexandria, Egypt, in the engineering stage. United Carbon India Ltd. expanded capacity of its Bombay, India, plant by 4,900 tons per year. Phillips Carbon Black Italiana S.p.A. increased capacity at its Milan, Italy, plant from 92.6 million to 114.7 million pounds per year. Continental-Columbian Carbon Nederland NV., subsidiary of Continental Carbon and Columbia Carbon Co., was increasing capacity of its Botlek-Rotterdam plant by 15,000 tons per year. Also, Phillips Carbon Black Co. Pty. Ltd. was expanding its Port Elizabeth, Republic of South Africa, plant from 56.7 million to 83.8 million pounds per year. Ashland Oil Canada Ltd. was constructing in Levis County, Quebec, a 40-million-pound-per-year carbon black plant. The French subsidiary of a U.S. joint venture of Phillips Petroleum Co. and Continental Carbon Co. was expanding its Bordeaux carbon black plant from 97 to 129 million pounds per year.

In Canada, Cantex Associates started construction of a 40-million-pound-per-year specialty carbon black plant in Medicine Hat, Alberta. The specialty thermal black, currently produced only in the southern United States, is used in rubber products with a growth market in a new generation of products now being manufactured. This new plant is expected to meet total Canadian demand, estimated to be about 20 million pounds in 1974 and serve export markets in the U.S. and Pacific countries. Presently all Canadian needs for specialty black are imported.

TECHNOLOGY

Carbon black, a petrochemical, is an extremely fine soot, primarily carbon (90 to 99%), that contains some oxygen and hydrogen. Oil furnace black may contain also small amounts of sulfur. The properties of carbon black are determined largely by the process by which it is manufactured. Furnace black, which accounts for 99% of all carbon black produced, is made by three different processes—oil furnace, gas furnace, and thermal. Brief descriptions of these processes, of the channel process, and of the manufacture of lampblack and acetylene black follow.

Oil Furnace.—In the oil furnace process, liquid hydrocarbons are used. Natural gas is generally burned to furnish the heat of combustion, and atomized oil is introduced into the combustion zone to be burned to various grades of carbon black. Yields range from 35 to 65%, depending on the grade of black produced. Oil furnace grades are GPF, FEF, HAF, ISAF, and SAF. (The full name of each grade is given in the footnotes to table 3.)

The most desirable feedstock oil for furnace black plants has zero to 4° API gravity and is low in sulfur and high in aromatics and olefins. It comes from near the "bottom of the refinery barrel" and is similar in many respects to residual fuel oil. The rising cost of natural gas has been a factor in the shift to greater use of liquid feedstocks and a decline in the use of natural gas as a source of carbon. At the same time, it should be recognized that oil furnace processing has become very flexible. Oil furnace blacks supplement channel blacks in most high-performance applications, notably passenger car tire treads. Over the past 2 decades, carbon black technology has centered on the oil furnace black process.

Gas Furnace.—The gas furnace process is based on partial combustion of natural gas in refractory-lined furnaces. Carbon black is removed by flocculation and high-voltage electric precipitators. Yields of the gas furnace blacks range from 10 to 30% and are lowest for the smaller particle-size grades. Properties of gas furnace blacks can be modified to a degree by changing the ratio of air to gas. The grades SRF and HMF are generally produced from gas. (The full name of each grade is given in the footnotes to table 3.)

Thermal.—Unlike channel and furnace blacks, thermal blacks are produced by cracking a hydrocarbon; that is, by separating the carbon from the hydrogen and not by the combustion of a hydrocarbon. Thermal furnaces are built in a checker-board brickwork pattern. Two refractory-lined furnaces, or generators, are used. One generator is heating, using hydrogen as a fuel, while the other generator is being charged with natural gas, which decomposes to produce thermal black and hydrogen. The hydrogen is collected and used as fuel for the generator being heated. Yields of carbon black are primarily in the large particle sizes and range from 40 to 50%.

Channel Black.—Made by the oldest process, channel black is a product of incomplete combustion of natural gas. Small flames are impinged on cool surfaces, or channels, where carbon black is deposited and then scraped off as the channel moves back and forth over a scraper. The properties of channel black are varied by changes in burner tip design, distances from tip to channel, and the amount of air made available for combustion. The process is extraordinarily inefficient chemically. For rubber-reinforcing grades, the yield is only 5%; for high-color blacks of finer particle sizes, the yield shrinks to 1%. Low yields and rising gas prices have spurred the industry to develop other methods to make blacks.

Lampblacks.—Lampblacks are manufactured by slowly burning selected oils and tars in a restricted supply of air. These blacks are of large particle size, possess little reinforcing ability in rubber, and are lower in jetness and coloring power. They are of value as tinting pigments in certain paints and lacquers. In most applications they have been replaced by carbon blacks.

Acetylene Black.—Acetylene blacks, produced by the thermal decomposition of acetylene, possess a high degree of structural, or chaining, tendency. Their particle size is about 40 micrometers. They provide high elastic modulus and high conductivity in rubber stocks.

A process for the manufacture of carbon black using highly volatile, vitrain-rich, low-ash coals of Assam has been developed at the Regional Research Laboratory, Jorhot, Assam, for the National Research Development Corp. of New Delhi, India. In the process, handpicked coal is crushed, finely ground, and flash decomposed. The product is subsequently treated in a fluidized-bed refractory reactor at a fixed temperature, with air as the fluidizing medium. After initial separation of the char in a cyclone separator, the carbon black can be recovered from the flue gases by water scrubbing and electrostatic precipitation. The carbon black is then pelletized and dried at a temperature of 300°–400° C. The yield is approximately 20%.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the People's Republic of China, Norway, Poland, and the U.S.S.R. produce carbon black, but available information is inadequate to make reliable estimates of output levels.

[2] Less than 1 million pounds.

Cement

By Brinton C. Brown [1]

Portland cement shipments from plants in the United States and Puerto Rico reached another alltime high of 81,432,000 tons in 1972, surpassing the 1971 record by 3%. Mill value rose to $1.65 billion, an increase of 12%, reflecting a unit increase of $1.57 a ton. A record 4.9 million tons of cement and clinker were imported for consumption in the United States and Puerto Rico, an increase of 59%. Cement sales were again spurred by an unprecedented high level of housing construction, particularly in the South. In Florida, for example, building permits increased 55%.

The cement situation in 1972 was a dichotomy of regional shortages and surpluses, with transportation costs a barrier to the solution of both problems. Imports doubled in Florida to alleviate an acute shortage, while domestic producers allocated shipments to customers in that area.

Although production capacity remained unchanged, consumption was rising, costs were escalating upward, and prices increased 8% despite constraints imposed under Phase II of the Economic Stabilization Act. Nevertheless, price increases did not offset rising costs of labor, fuel, power, transportation, and materials. Manufacturers complained that profits were inadequate to provide capital for reinvestment and new plant investment. With the improved demand for cement some companies ameliorated their profit position by operating plants at or near capacity. The real improvement was from the increased volume of cement shipped. Hurricane Agnes in June and exceptionally bad weather in the fourth quarter curtailed cement shipments and prevented sales from reaching an even greater record high.

Curtailed cement production stemming from a natural gas shortage impelled 16 companies to install alternate standby fuel systems. Several companies were investing in natural gas supplies. Kaiser Cement & Gypsum Co. purchased two gas wells and

[1] Excludes Puerto Rico.
[2] Includes portland, masonry, and slag cement (1968–1969). Excludes slag cement (1970–1972).
[3] Includes imported cement shipped by domestic producers only.
[4] Value received, f.o.b. mill, excluding cost of containers.
[5] Includes portland, masonry (1970–1972), slag cement (1968–1969).
[6] Quantity shipped plus imports minus exports.
[7] Adjusted to eliminate duplication of imports (clinker and cement) shipped by domestic cement manufacturers.

---

[1] Mining engineer, Division of Nonmetallic Minerals—Mineral Supply.

may acquire additional gas wells for its Longhorn plant in Texas. Lone Star Industries, Inc. was undertaking a natural gas exploration and development program in New Mexico and Texas to assure gas supplies for manufacturing cement. Because of the shortage of low-sulfur coal more companies changed from coal to fuel oil. Nevertheless, an impending fuel oil shortage had many companies investigating the use of low-sulfur coal from western States for standby fuel. The cost of all fuels was increasing.

Several plants completed air pollution control projects during the year to comply with present standards and regulations. Most of the plants in the country were modernizing and improving the efficiency of dust-collecting facilities. Many companies were financing pollution control facilities through tax-exempt bonds and securities issued by municipalities and local government agencies. Companies will repay under a lease arrangement with the local governments. These bond issues represented an effective means to raise capital at relatively low cost for essential, but nonproductive, equipment.

In 1972 four new kilns started operation with a combined annual capacity of 1.5 million tons. But by yearend 13 old kilns were permanently removed from service, so the production capacity of the industry remained virtually unchanged. Several new plants and many plant expansion and modernization programs were in various stages of planning and construction.

In response to the Portland Cement Association's (PCA) request for an industry-wide price relief the Price Commission held a public hearing in Houston, Tex. on October 6. The Commission received information regarding price controls and related problems of industry capacity, supply shortages, costs, profitability, and capital investment in the cement industry. No decision had been made by yearend.

The year 1972 marked the first full one of experience with a newly developed system of reporting injuries and illnesses under the Williams-Steiger Occupational Safety and Health Act of 1970. The Ideal Cement Co. plant at Portland, Colo., was the leader in the PCA safety honor awards for 1972, working 3,400 consecutive days without a lost-time or disabling injury. Universal Atlas Cement Div. of United States Steel Corp. plants at Leeds, Ala., and Waco, Tex., also completed more than 3,000 accident-free days. Members of the PCA competition with more than 2,000 consecutive days without injuries were: Hawaiian Cement Corp. at Ewa Beach, Oahu; Louisville Cement Co. at Logansport, Ind.; Lone Star Industries at Demopolis, Ala.; and Universal Atlas Cement at Hannibal, Mo. The Manitowoc, Wisc., plant of Medusa Cement Co. received the PCA Twenty-fifth Safety Trophy Reaward for 26 accident-free years (not consecutive). Lone Star Industries plants at Birmingham, Ala., and New Orleans, La., received the PCA Twenty-first Safety Trophy Reaward for 22 years without lost-time injuries.

Legislation and Government Programs.—Two Federal laws were enacted that directly affect environmental aspects of the cement industry. Public Law 92–500, the Federal Water Pollution Control Act Amendments of 1972, effective October 18, extends Federal responsibility from interstate waters to all U.S. waters; calls for States to retain primary responsibility but provides for Environmental Protection Agency (EPA) intervention if States fail to act; requires more stringent effluent limits; requires the EPA to establish guidelines and water quality standards; provides for a permit program to replace the 1899 Refuse Act permit program; provides for penalties up to $50,000 a day and 2 years in prison for second offenses; and specifies dozens of other key provisions. The $24.5 billion authorizations contained in the 98-page act represent the largest single public works program authorization since the enactment of the Federal Interstate Highway Program. Pollutant permit activity administered by the Corps of Engineers under the 1899 Refuse Act was superseded, but the Corps' authority to issue dredge and fill permits was continued.

Public Law 92–574, Environmental Noise Control Act of 1972, effective October 27, directs the EPA to set and enforce noise standards for certain equipment. Provisions of the Occupational Safety and Health Act were designed to eliminate the possibility of hearing loss in three ways: (1) by taking the initial step and making a sound survey; (2) engineering noise out; and (3) using protective devices to reduce noise levels. The Occupational Safety and

Health Administration (OSHA) conducted tests that prove noise levels exceeding 90 decibels (dba) are potentially harmful. Some environmentalists were exerting pressure on the EPA to set 85 dba as the acceptable limit rather than 90 dba. In the cement industry, raw and finish-grinding mills produce 102–105 dba and diesel trucks in quarry operations register 94 dba.

The PCA in a suit against the EPA charged that the new standards established for cement plants under provisions of the Clean Air Act were promulgated without the Administrator's compliance with the National Environmental Policy Act of 1969. Furthermore, the PCA challenged the Administrator on grounds that economic costs were not adequately taken into account and that the standards unfairly discriminate against portland cement plants, in comparison with standards promulgated for powerplants and municipal incinerators. The PCA charged that the achievability of the standards was not adequately demonstrated. The United States Court of Appeals for the District of Columbia Circuit had not given an opinion by yearend. However, the EPA published in the August 25 Federal Register a notice of proposed rule making issued under the authority of the Clean Air Act. Part 60, title 40, Code of Federal Regulations was proposed to be amended by adding a new section, 60.11, dealing with assertedly excusable violations regarding emissions during startup, shutdown, and malfunction of kilns.

Under new Treasury Department regulations a company mixing ammonium nitrate fertilizer with fuel oil as needed to blast limestone in a quarry is considered an explosives manufacturer and a Federal license is required. The regulations, part 181 of title 26 of the Code of Federal Regulations define a manufacturer-limited as any person engaged in the business of manufacturing explosive materials for his own use and not for sale or distribution. A manufacturer-limited license costs $5 and a separate fee is required for each business location.

The Federal Trade Commission (FTC) docket No. C–2375 alleges that the St. Lawrence Cement Co. acquisition of Wyandotte Cement Inc. violates section 7 of the Clayton Act, particularly in view of the Holderbank Financiere Glaris S.A. financial interest in St. Lawrence Cement Co. and Dundee Cement Co., both marketing in the same area. St. Lawrence Cement Co. agreed to sell its assets in Wyandotte, Mich., effective December 31, 1973.

In a February decision, the U.S. Court of Appeals for the Tenth Circuit upheld the FTC order (docket No. 8802) that OKC Corp. divest its interest in Jahncke Service, Inc., a producer of ready-mix concrete. Missouri Portland Cement Co., in a prolonged controversy with the FTC (docket No. 8783), entered into a consent agreement that calls for divestiture of Botsford Ready Mix Co. Lehigh Portland Cement Co. entered into a consent agreement with the FTC in June disposing of the company's holdings in ready-mix concrete companies in Florida, Kentucky, and Virginia. The Kentucky and Virginia subsidiaries were sold. By mid-1974 the company must decide whether to sell the Miami cement plant and keep all 11 ready-mixed concrete plants, or keep the cement plant and sell six ready-mix plants.

Environmental Activities.—During the 10-year period through 1971, approximately $216 million was spent by the cement industry in the United States on capital equipment for air and water pollution control. The EPA estimates that capital expenditures during the period 1972 through 1976 required to bring existing plants into full compliance with present standards and regulations will be $97 million for air pollution abatement and $25 million for water pollution control. Additional millions of dollars will be expended for pollution control facilities installed at new plants and plant expansions under construction. Pollution control facilities comprise 10% to 15% of the capital cost of a new plant, or $5.00 to $6.50 a ton of annual production capacity. The EPA estimates the annual costs of operating pollution control facilities in the cement industry will increase from $3 million in 1972 to $43 million in 1976. This will average about 42 to 53 cents a ton of cement produced. Members of the industry estimate the upper figure to exceed $1.00 a ton.

Many companies petitioned local pollution control agencies to operate plants under variances from the standards and regulations until pollution control facilities could be engineered and installed. To mention a few, Ideal Cement Co. received variances for the following plants: San Juan Bautista, Calif., from the San Benito County Air Pollution Hearing Board; Ada, Okla., from the Oklahoma Air Pollution Control Division; Portland, Colo.; Devils Slide, Utah; and Trident, Mont. The Illinois Pollution Control Board granted a variance to Marquette Cement Manufacturing Co. for its Oglesby, Ill., plant. The Arizona Air Pollution Control Hearing Board granted a 1-year extension to Arizona Portland Cement Co. to operate its Rillito, Ariz., plant under a variance. The Minnesota Pollution Control Agency extended its deadline to July 1974 for Universal Atlas Cement Division of United States Steel Corp. to meet State standards.

Some companies failing to meet standards were cited. The South Carolina Pollution . Control Authority issued orders against Santee Portland Cement Co. and Giant Portland Cement Co., located near Holly Hill, S.C. which require the firms to meet all State air quality standards by March 30, 1974. The Michigan Air Pollution Control Commission issued an order to the Huron Cement Div. of National Gypsum Co. setting forth a compliance schedule for elimination of dust emissions from kilns at the company's Alpena, Mich., plant. The order was complied with on four kilns, but the company determined that it was not economical to install collectors for the remaining 12 kilns where dust elimination was required.

Other companies were defendants in legal actions. In a Consent Judgment settling legal proceedings instituted against the American Cement Corp. at its Detroit, Mich. plant by the City of Detroit and Wayne County, the company spent $350,000 on pollution control facilities. Completion of air pollution abatement projects at the General Portland Inc. plant in Chattanooga, Tenn., not only alleviated legal pressure but the company was recognized by the Chattanooga-Hamilton County Air Pollution Control Board as one of four companies that have met 1974 regulations 2 years ahead of schedule. Legal actions against General Portland in Tampa, Fla., by the State were settled. When construction is completed by mid-1973, the Tampa plant should be in compliance with all regulations and the litigation instituted by the county should be resolved.

While Nevada Cement Co. and its parent firm, Centex Corp., Dallas, Tex., have appealed to the Nevada Supreme Court to reverse a district court's decision awarding $1,865,298 to 85 residents in Fernley, Nev., a second suit was filed on March 6, 1972. This suit was filed by 9 individuals in the District Court of Lyons County purportedly as a class action alleged to include some 2,000 persons seeking nearly $43 million.

In November, Harris County, Tex., as plaintiff, brought suit against Ideal Cement Co., alleging that at its Galena Park cement plant operations, wastes were discharged into waters of the State of Texas in contravention of its waste discharge permit and of orders, rules, and regulations of the Texas Water Quality Board. Representatives of the Midcoastal Sportsmen's Club and the National Audubon Society filed protests against an application by Lone Star Industries Inc. for additional permits to dredge oyster shells at several new locations in San Antonio Bay. Only conditional permits were being issued while awaiting results of a study being conducted by Texas A&M University in cooperation with the Texas Parks and Wildlife Department. The study was ordered by the Corps of Engineers because of protests in past years over possible damage to the environment resulting from shell dredging in Texas coastal waters.

Keystone Portland Cement Co. was helping maintain a regular flow in Monocacy Creek by pumping water into it from its Bath, Pa., quarry. Sections of the creek in Northampton County had been dry and the quality of the quarry water is good so it posed no danger to aquatic life. National Portland Cement Co. filed a permanent plan to treat the effluent from the wet scrubber system at its Brodhead, Pa., plant to assure that water will not harm aquatic life in Monocacy Creek. The company plans to donate $10,000 to the State of Pennsylvania for the improvement of streams.

At its Permanente, Calif. operation Kaiser Cement & Gypsum Corp. granted the Santa Clara County Board of Supervisors an easement deed guaranteeing preservation of Permanente Ridge against quarrying below the 1500-foot level to maintain the scenic backdrop for county residents. The company retained a landscape architectural firm to develop a program of revegetation for sections of the quarry in which mining was completed. The 5-year program calls for the use of oaks, California Bay trees, manzanita, and other shrubs, trees, and grasses native to the surrounding area. While beautification work is undertaken by companies in the U.S., employees at all levels in the cement plants in Russia were expected to contribute at least 20 hours annually for planting. The Angarsk cement plant received the Government's "Protection of Russia's Nature" medal for landscaping the grounds with 40,000 trees, 50,000 shrubs, and flowerbeds. Waste heat from the kilns was utilized in greenhouses to grow vegetables. Ciments Lafarge's new plant at Port la Nouvelle received an award worth F10,000 from the French Minister of the Environment for protection of the landscape and dust and noise control. Twelve percent of the capital cost of this plant was spent on pollution control.

After conducting waste reclamation tests using an idle kiln at Alpha Portland Industries' old plant in LaSalle, Ill., All American Environmental Control Corp. (AENCO) of Wilmington, Del., purchased the idle Lehigh Portland Cement Co. Fordwick plant near Craigsville, Va. AENCO proposed to solve the Washington, D.C., metropolitan area solid waste disposal problem by processing at least 500 tons of refuse a day. In addition to reclaiming metallic wastes, AENCO planned to start a mushroom growing center using constituents of the processed waste as compost. Despite public clamor by ecologists and environmentalists about solid waste disposal, no one in the Nation's Capital was willing to supply waste to operate the plant. Solid wastes from the metropolitan areas of Baltimore, Md., and Richmond, Va., could not be obtained either.

A court action that could adversely affect cement sales in the construction sector occurred on September 21 when the California Supreme Court, in a 6 to 1 decision, decreed that State and local governmental agencies must file written environmental impact statements on applications for private as well as public construction projects that may affect the environment under the State Environmental Quality Act. The decision will allow citizens to sue to halt any significant private construction project that doesn't have an environmental impact study. Acting on the advice of city attorneys, many communities curtailed or completely stopped the issuance of building permits, even for repairs to existing structures, pending interpretation of the Court's ruling or action by the State Legislature. Other States were expected to follow California's lead.

EPA testimony at the Price Commission Hearing in Houston, Tex., estimated that electrostatic precipitators cost about $1 million each and fabric bag dust collectors cost approximately $600,000 each. Although the following lists are not complete they give an indication of the millions of dollars expended or committed by the cement industry for air pollution control equipment and installation.

Electrostatic precipitators were installed or under construction by the following companies, with the number in parentheses: Alpha Portland Industries, Inc. at Birmingham, Ala. (2), and Jamesville, N.Y. (1); Arkansas Cement Corp. at Foreman, Ark. (3); Ash Grove Cement Co. at Louisville, Neb. (1); Dundee Cement Co. at Dundee, Mich. (4); General Portland Inc. at Chattanooga, Tenn. (1), and Fort Worth, Tex. (1); Hawaiian Cement Corp. at Barber's Point, Hawaii (1); Ideal Cement Co. at Knoxville, Tenn. (3), Okay, Ark. (2), Portland, Colo. (2), Devils Slide, Utah (2), and Trident, Mont. (1); Lone Star Industries, Inc. at Birmingham, Ala. (1), and New Orleans, La (2); Louisville Cement Co. at Bessemer, Pa. (1); Marquette Cement Manufacturing Co. at Oglesby, Ill. (1); National Cement Co. Div. of Mead Corp. at Ragland, Ala. (1); Columbia Cement Co. Div., PPG Industries, Inc., at Zanesville, Ohio (2); and Santee Portland Cement Co. at Holly Hill, S.C. (3).

Glass baghouse dust collectors were installed or were under construction at kiln operations by the following companies, with the number in parentheses: Coplay Cement Manufacturing Co. at Egypt, Pa. (6); Giant Portland Cement Co. at Harleyville, S.C. (2); Hawaiian Cement Co. at Barber's Point, Hawaii (1); Kaiser Cement & Gypsum Corp. at Permanente, Calif. (2), and Lucerne Valley, Calif. (3); Martin Marietta Cement at Buffalo, Iowa (1), and Calera, Ala. (2); and Whitehall Cement Mfg. Co. at Cementon, Pa., replaced an electrostatic precipitator with a glass baghouse.

Air and water pollution control equipment was installed or under construction by the following companies with dollar values in millions, if announced: American Cement Corp. at Detroit, Mich. (3.1); Colonial Sand and Stone Co. at Kingston, N.Y. (2.5); Gifford-Hill & Co. Inc. at Midlothian, Tex., and Harleyville, S.C. (3.5); Kaiser Cement & Gypsum Co. at Waianae, Hawaii (0.4); Lehigh Portland Cement Co. at Alsen, N.Y. (4.0), and Mason City, Iowa (2.0); Louisville Cement Co. at three plants (4.4); Marquette Cement Manufacturing Co. at several plants (6.7); Medusa Corp. at Clinchfield, Ga. (3.9); Huron Portland Cement Div. of National Gypsum Co. at Alpena, Mich. (2.5); OKC Corp. at Pryor, Okla., and New Orleans, La.; Universal Atlas Cement Div. of United States Steel Corp. at Hannibal, Mo., Waco, Tex., and Independence, Kans.; and Wyandotte Cement, Inc., at its grinding plant in Wyandotte, Mich. (0.75).

DOMESTIC PRODUCTION

PORTLAND CEMENT

Manufacturers in the United States and Puerto Rico produced 77,378,000 tons of clinker and imported 1,691,000 tons of foreign clinker to grind an alltime record 80,744,000 tons of portland cement. Domestic producers shipped 81,432,000 tons of portland cement which included 1,512,000 tons of imported cement. Stocks increased about 600,000 tons. In addition to the imported cement shipped by domestic manufacturers, 1.6 million tons of portland cement was imported and shipped or used by others not producing cement in the United States and Puerto Rico.

Production Capacity.—Four new kilns were brought into production with a combined annual capacity of 1.5 million tons, and five old kilns were reactivated at four plants in 1972. However, 13 old kilns were permanently removed from production at four plants by yearend and the total annual production capacity remained virtually the same as in 1971.

At yearend 461 kilns were in operation at 169 plants in 41 States and Puerto Rico with an estimated 24-hour-daily clinker production capacity of 256,000 tons. An average of 31 days downtime was reported for kiln maintenance and replacing refractory bricks, so based on 334 days of operation, the apparent annual clinker production capacity of the industry was 85.4 million tons.

In addition to 169 clinker-producing plants, including eight white cement facilities, six plants operated grinding mills only, on imported, purchased, or interplant transfers of clinker. Information was not collected on grinding capacity, but the total in the United States and Puerto Rico was estimated to be 94 million tons.

The following tabulation shows the daily clinker production capacities of cement plants in the United States and Puerto Rico, grouped according to relative size:

Daily clinker capacity, December 31

Short tons per 24-hour period	Number of plants [1]	Kilns [2]	Total capacity	Percent of total capacity
1971:				
Less than 600	6	10	2,671	1.0
600 to 1,150	49	98	40,455	15.8
1,150 to 1,700	65	170	88,927	34.6
1,700 to 2,300	28	95	54,303	21.1
2,300 to 2,800	11	37	28,734	11.2
2,800 and over	11	56	41,772	16.3
Total	170	466	256,862	100.0
1972:				
Less than 600	10	17	4,860	1.9
600 to 1,150	47	93	40,646	15.9
1,150 to 1,700	60	175	80,808	31.5
1,700 to 2,300	29	78	55,384	21.6
2,300 to 2,800	9	31	22,646	8.8
2,800 and over	14	68	52,073	20.3
Total	169	461	256,417	100.0

[1] Includes white-cement-producing facilities.
[2] Total number in operation at plants.

Capacity Changes.—On March 30th, Texas Industries, Inc., started to produce clinker from its new fourth kiln at Midlothian, Tex. The 12-foot by 450-foot wet-process kiln increased plant annual capacity by 301,000 tons to a total of 1.2 million tons. Also included in the expansion was a 12-foot by 33-foot finish-grinding mill completed in April. Gifford-Hill Portland Cement Co. increased the annual capacity of its Midlothian plant to 846,000 tons with the addition of a third kiln. The new 12-foot by 450-foot kiln with an annual capacity of 282,000 tons went on stream in July. Hawaiian Cement Corp. installed a 12-foot by 191-foot kiln equipped with a suspension preheater and the first modern planetary clinker cooler in the United States. The $6 million expansion project completed in July 1972 near Ewa Beach, Oahu, increased annual clinker production capacity by 271,000 tons to a total of 451,000 tons. The original smaller kiln may be used for specialty cements. Additional grinding capacity was planned.

In September, Arizona Portland Cement Co. started operating a new kiln with a suspension preheater, the largest presently installed in the U.S., at its Rillito, Ariz., plant. The kiln, 15 feet in diameter by 235 feet long, has a daily production capacity of 1,880 tons. One old kiln was shut down permanently and the other two older kilns were in the process of being modernized, particularly in the dust-collecting facilities. A new finish-grinding mill was being installed. When completed in January 1974, the plant will have an annual capacity of 1.15 million tons compared with 500,000 tons in 1971 prior to the new construction. Included in the $20 million expansion and modernization program was a 1000-ton-per-hour Hazemag impact crusher; a 30-inch, 4.8 mile long belt conveyor totally enclosed; an enclosed raw material storage area; and a 15.5-foot by 21-foot, 3000-hp raw-grinding mill. An expansion to the feed end of a kiln at the Martin Marietta Corp. plant in Atlanta, Ga., increased annual capacity by 75,000 tons.

In addition to the four new kilns becoming operational during the year, five old kilns were reactivated. In March, Coplay Cement Manufacturing Co. purchased the Giant Portland Cement Co. plant at Egypt, Pa., that was closed in 1970. The Egypt plant is adjacent to the company's Coplay plant. Two of the eight kilns with a combined annual capacity of 112,000 tons were placed into operation by midyear. Installation of preheaters on kilns at the company's Nazareth, Pa., plant increased output capacity by 64,000 tons. A kiln shut down several years ago at Alsen, N.Y., was reactivated by Lehigh Portland Cement Co. and increased production capacity by 20%. Oregon Portland Cement Co. reactivated the older kiln at its Lime, Oreg. plant and installed a new coal mill at its operation. Allentown Cement Div. of National Gypsum Co. reactivated an old kiln at its Evansville, Pa., plant.

Puerto Rican Cement Co., Inc. converted its white cement facilities at Ponce, P.R., to gray cement production at yearend.

In April, Lone Star Industries, Inc., discontinued kiln operations at its Norfolk, Va., plant, but continued to operate grinding mills on imported clinker. In October, Peerless Cement Co. Div. of American Cement Corp. suspended manufacturing operations at its Brennan Avenue plant in Detroit, Mich. Future plans are to incorporate the 16-year-old facility into the new Detroit plant complex. The company also closed the Port Huron, Mich., plant at yearend.

Planned Expansions and New Plants.—Twelve plant modernizations and expansions were under construction and scheduled for completion in 1973. At Oglesby, Ill., Marquette Cement Manufacturing Co. was replacing eight old kilns shut down in December with one kiln that would increase the annual capacity by 28,000 tons to a total of 771,000 tons when completed in January 1973. One new 13-foot by 43-foot, 4400-hp finish-grinding mill replaced 12 old mills. In a $15 million project Glens Falls Cement Co., Div. of the Flintkote Co. was converting its Glens Falls, N.Y., plant from wet to dry process with the installation of a 15-foot-diameter by 235-foot-long kiln equipped with a Miag 220-foot-high, four-stage counterflow suspension preheater. The new kiln, expected to be operational by July 1973, will increase the clinker production capacity by 244,000 tons to a total of 564,000 tons.

Giant Portland Cement Co. was installing a new fifth kiln at Harleyville, S.C., that will increase annual capacity by 280,000 tons to a total of 1,032,000 tons when completed in mid-1973. In addition to the 12.5-foot diameter/11.25-foot-diameter/13-foot-diameter by 425-foot-long wet-process kiln, a 10-foot-diameter by 32-foot-long raw-grinding mill, and a 12-foot by 32-foot finish-grinding mill were included in the $9 million expansion program. The company plans to discontinue operation of the oldest kiln. Ideal Cement Co. was converting the Trident, Mont. plant from dry to wet process with the installation of one new 12-foot-diameter by 450-foot-long kiln to replace four old kilns. When completed in April 1973, the annual capacity will be increased by 38,000 tons to 329,000 tons. Computer controls were included in the $12 million expansion project. At Speed, Ind., Louisville Cement Co. was replacing three old kilns with one new kiln 13 feet/15 feet in diameter by 500 feet long. The clinker production capacity will be increased by 197,000 tons to a total of 1,109,000 tons when completed in the first quarter of 1973.

Monarch Cement Co. started construction of a new dry process kiln with a preheater at Humboldt, Kans., to replace some old kilns. The 12-foot-diameter by 165-foot-long kiln with a daily capacity of 800 tons was scheduled for completion in late 1973. A second identical kiln was planned for operation in 1975. A new Preliminator grinding mill was installed during the year. The Phoenix Div. of American Cement Corp. completed an expansion program including a 1500-hp finish-grinding mill at Clarkdale, Ariz., that increased the annual capacity by 150,000 tons to a total of 660,000 tons. At Miami, Fla., General Portland, Inc., was modifying two kilns 11.5 feet in diameter by 425 feet long by replacing sections of the kiln shell at the feed end with enlarged shells 13 feet in diameter by 126 feet long. The project, scheduled for completion in 1973, will increase the annual clinker production capacity by 56,000 tons to a total of 483,000. Coplay Cement Manufacturing Co. started installation of a glass baghouse in order to reactivate six remaining kilns at its recently purchased Egypt, Pa., plant, now an integral part of the Coplay plant. When completed by the summer of 1973, the annual capacity of the new plant complex will be increased by 260,000 tons to a total of 1,350,000 tons. Lehigh Portland Cement Co. planned to reactivate two old kilns at Alsen, N.Y., when construction to meet environmental standards is completed in 1973.

Construction was started on a kiln modification project by OKC Corp. at its Pryor, Okla., plant that will increase annual capacity by 75,000 tons to a total of 451,000 tons when completed in late 1973. The company also started a $15 million expansion project at its New Orleans, La., plant. Annual capacity will be increased by 357,000 tons to a total of 677,000 tons by the addition of a 14-foot/12.5-foot-diameter by 460-foot-long kiln and two grinding mills, 12 feet by 36 feet, one for raw feed and the other for finished cement. Completion was scheduled for late 1973.

San Juan Cement Co. started construction to expand its plant in the Barrio Espinosa area of Dorado near San Juan, P.R. The wet process kiln 12 feet/13.5 feet in diameter by 471 feet long will increase the annual capacity by 282,000 tons to a total of 752,000 tons when completed. Equipment to be installed also includes an 11-foot by 38-foot raw-grinding mill and a 13-foot by 42-foot, 4000-hp finish-grinding mill.

Three new plants were under construction or planned for operation in 1974. Gifford-Hill Portland Cement Co. started construction of a new $26 million plant at Harleyville, S.C. The 15-foot-diameter by 220-foot-long kiln equipped with a suspension preheater will have an annual capacity of 564,000 tons when completed in January 1974. Also scheduled for operation in January is a $15 million plant at Columbus, Miss., by Texas Industries, Inc. Initial capacity will be 376,000 tons, with provisions to expand the annual capacity to 1.1 million tons. In July 1972 Centex Cement Corp. purchased the old plant of Alpha Portland Industries, Inc. at LaSalle, Ill. The company was installing a 13.5-foot-diameter by 190-foot-long kiln equipped with a four-stage suspension preheater and an 11-foot by 34-foot finish-grinding mill. The plant, scheduled for operation in early 1974, will have an annual capacity of 376,000 tons.

Plans for an additional 13 plant modernization and expansion program were announced. These were in various stages of planning and construction, and completion was scheduled for 1974 or 1975. Medusa Corp. started construction on a $13 million expansion project at Clinchfield, Ga. A

15-foot-diameter by 220-foot-long kiln equipped with a suspension preheater having an annual capacity of 560,000 tons will be installed along with grinding mills. Completion was scheduled for January 1974. Old kilns with a combined capacity of 200,000 tons will be retired, so that the annual clinker production capacity will be increased by 360,000 tons to a total of 752,000 tons. Santee Portland Cement Co. was expanding its Holly Hill, S.C., plant with the addition of a new 18 feet in diameter by 580 feet long kiln. Also included in the $12 million project were an 11-foot by 38-foot raw-grinding mill and a 13-foot by 46-foot finish-grinding mill. When completed in early 1974, the annual capacity will be increased by 752,000 tons to a total of 1,128,000 tons. The Diamond-Kosmos Cement Div. of the Flintkote Co. planned a $25 million modernization and expansion of its Kosmosdale, Ky., plant for completion in mid-1974. The new kiln, with an annual capacity of 658,000 tons, will replace four old kilns in operation now and six old kilns shut down in 1970. This will increase the plant's clinker production capacity 50% from the present capacity and 10% above the 1970 capacity.

At Portland, Colo., a $25 million expansion project was under construction for Ideal Cement Co. that will double the annual capacity to 936,000 tons. Equipment to be installed includes a 16.5-foot-diameter by 500-foot-long kiln, wet process, and three 11-foot by 34-foot grinding mills, one for raw feed and two for finished cement. Completion was scheduled for mid-1974. Pennsuco Cement and Aggregates, Inc., subsidiary of Maule Industries, Inc., completed installation of a new 4,000-hp, 13-foot by 43-foot finish-grinding mill in November 1972 at its plant near Miami, Fla., and started operating it on imported clinker. A new wet-process kiln will be installed to increase annual clinker production capacity from 432,000 tons to 1,222,000 tons when completed in 1974. The company has ordered a 6,300-hp grinding mill to be installed early in 1975 that will increase the grinding capacity from 1,222,000 tons to 2,162,000 tons. Southwestern Portland Cement Co., subsidiary of Southdown, Inc., started construction of new facilities at Fairborn, Ohio, to replace the 47-year-old plant. The $17 million project includes a 15-foot-diameter by 220-foot-long kiln equipped with a suspension preheater. The kiln has an annual capacity of 620,000 tons. When completed in 1974 the company expects a 20% increase over present production output with a 40% decrease in fuel consumption.

Ash Grove Cement Co. planned to replace five old wet-process kilns built in 1929 with a new dry-process kiln at its plant in Louisville, Neb. When completed in late 1974 or early 1975 the annual capacity will be increased by 282,000 tons to a total of 936,000 tons. Whitehall Cement Manufacturing Co. planned to install a kiln equipped with a preheater and with an annual capacity of 235,000 tons. The $9 million expansion program, including a 3,500-hp finish-grinding mill scheduled for completion by mid-1975, will increase the annual capacity of the Cementon, Pa., plant by 45%.

Puerto Rican Cement Co. was planning to construct a $30 million plant near Toa Alta, about 15 miles southwest of its San Juan plant. This will replace the four kilns at the 33-year-old San Juan facility having a combined annual capacity of 564,000 tons. The near depletion of limestone reserves at the old plant and the uneconomic feasibility of meeting the Federal Air Pollution control standards by 1975 were the compelling reasons for the new plant.

Coplay Cement Manufacturing Co. planned additional kiln capacity in 1975 at its Coplay, Pa., plant. This would bring the combined total annual clinker production capacity of the Coplay-Egypt plant complex to 1,430,000 tons. Monolith Portland Cement Co. installed a new crusher and conveyor belt at its quarry near Tehachipi, Calif., completing the second phase of a modernization program. A 15-foot/17.5-foot-diameter by 520-foot-long wet-process kiln with an annual capacity of 470,000 tons was scheduled for operation in 1974. Five old kilns will be retired and a second kiln will double the above capacity when installed in 1976. Southeastern Materials, Inc., planned to build a $28 million cement plant at the Pennsuco Industrial Center near Miami, Fla. The dry-process kiln equipped with a four-stage suspension preheater would have a daily capacity of 1,000 tons of clinker. Originally scheduled for completion in 1975, construction was initially delayed because of the indecision of the Dade County Pollution Control Board to issue a permit. Rinker Materials Corp. of West Palm Beach, Fla., owns a large share of the company.

Cement Grinding Facilities.—Clinker-grinding facilities were becoming increasingly important as quasi cement production units. The old Jefferson Avenue plant of American Cement Corp. in Detroit, Mich., purchased by Detroit Edison Co., was sold in June 1972 to Edward C. Levy Co. operating under the name Jefferson Marine Terminal. Cement will be produced by grinding clinker imported from Sweden and Canada in early 1973. The Norfolk, Va., plant of Lone Star Industries became a grinding facility when the kilns were shut down in April, and now operates on imported clinker. Pennsuco Cement and Aggregates, Inc., started grinding imported clinker in November at its plant near Miami, Fla. with a new grinding mill rated at 1,800 tons a day. When the new kiln is completed in 1974, the company plans to install an additional grinding mill in 1975 with an annual capacity of 940,000 tons to operate on imported clinker. Pesco Cement Co., a subsidiary of National Portland Cement Co., planned to install an 11-foot by 34-foot grinding mill at Bradenton's port, Manatee, Fla. The new plant, with an annual capacity of 282,000 tons was expected to be in operation by yearend 1973, grinding clinker imported from Europe.

River Cement Co. was installing a 13-foot by 34-foot, 3,500-hp finish-grinding mill with an annual capacity of 178,000 tons for completion in late 1973. This addition will bring the grinding capacity up to the clinker production capacity of 1,128,000 tons at its Festus, Mo., plant. Hawaiian Cement Corp. planned to install additional grinding facilities at Barber's Point, Hawaii to increase the present grinding capacity of 185,000 tons to equal the clinker production capacity of 450,000 tons. Capitol Cement Div. of Capitol Aggregates, Inc., installed a new 12-foot by 33-foot finish mill at its plant in San Antonio, Tex. Gulf Coast Portland Cement Co. was installing an 11-foot by 34-foot finish mill at its plant in Houston, Tex. Completion was scheduled for mid-1973. At Bath, Pa. Keystone Portland Cement Co. installed a new raw-grinding mill in late 1972 and converted the old raw mill to finish grinding. Missouri Portland Cement Co. was installing a new finish mill at its Joppa, Ill., plant. The 13-foot by 32.75-foot, 3,000-hp mill was scheduled for operation in June 1973.

Monarch Cement Co. completed installation of a new $800,000 Preliminator mill at its plant in Humboldt, Kans. Arizona Portland Cement Co. was replacing five 500-hp finish mills with one 14-foot by 24-foot, 3,000-hp grinding mill. When completed in December 1973, the annual grinding capacity of the Rillito, Ariz. plant will be 1,128,000 tons.

In addition to these grinding plants the following companies operate grinding facilities on imported, purchased, or interplant transfer of clinker: Wyandotte Cement, Inc., at Wyandotte, Mich.; Universal Atlas Cement Div. of United States Steel Corp. at Milwaukee, Wisc.; Huron Cement Div. of National Gypsum Co. at Superior, Wisc.; Allentown Cement Div. of National Gypsum Co. at West Conshohocken, Pa.; and G. & W. H. Corson, Inc., at Plymouth Meeting, Pa.

MASONRY CEMENT

Shipments of masonry cement again reached an alltime high of 3,850,000 tons, an increase of 13% over the 1971 record. The unit price increased $1.23 a ton to $26.52 and the total value increased 19% to $102.1 million. By yearend 116 plants were manufacturing masonry cement in the United States. Four plants produced masonry cement exclusively: Riverton Lime & Stone Co., Inc., Riverton, Va.; M. J. Grove Lime Co. Div. of Flintkote Co., Frederick, Md.; Cheney Lime and Cement Co., Allgood, Ala.; and Martin Marietta Cement, Birmingham, Ala. Riverton reported increased sales of colored masonry cement. In some States masonry cement was not produced because the majority of the masons preferred to purchase portland cement and add clay or lime for plasticity on the job. Masonry cement imports were 103,855 tons in 1972, nearly double the 1971 total.

ALUMINOUS CEMENT

Lone Star Lafarge Co. was constructing a $3 million grinding facility to produce calcium aluminate cement at Norfolk, Va. Equipment to be installed includes an 8.5-foot by 40-foot grinding mill and a 1,000-

ton-per-hour clinker receiving facility. Completion was scheduled for the spring of 1973. Lone Star Industries, Inc., in a joint venture with Ciments Lafarge, S.A., of France and Lafarge Organisation, Ltd., of England, will import clinker and market the cement under the name "Fondu." The Aluminum Co. of America operates a calcium aluminate cement plant at Bauxite, Ark., and Universal Atlas Cement Div. of United States Steel Corp. operates a calcium aluminate refractory cement plant at Gary, Ind.

TRANSPORTATION

Many companies reduced their marketing area in order to lower transportation and distribution costs through selective marketing during the President's Phase II price freeze. Prior to this, about 20% of the cost of cement to the buyer represented delivery expense from the mill. Testimony at the Price Commission hearing indicated that transportation costs could be as much as 25% of the delivered price.

Some companies closed cement distribution terminals to reduce costs, while others were building terminals for the same reason. Lehigh Portland Cement Co. closed its distribution terminal at Jacksonville, Fla., and General Portland Inc. was planning construction of a terminal adjacent to deep water in 1973 at Jacksonville. Lehigh opened the former Lone Star Industries terminal at Port of Pasco, Wash., in July. Ideal Cement Co. permanently discontinued its distribution facilities at Eugene, Oreg. After losing a barge at sea, Atlantic Cement Co. sold its terminal in Florida. The company added four silos at its Boston, Mass., distribution facility, increasing storage capacity 30,000 tons. Alpha Portland Industries Inc. sold its terminal in Chicago, Ill., to Centex Cement Corp. in July. Penn-Dixie Cement Corp. closed terminals at Memphis, Tenn., Buffalo, N.Y., and Minneapolis, Minn., during the year. South Dakota Cement Commission had a new $700,000 distribution center under construction in Sioux Falls, S. Dak. In addition to four silos with a total capacity of 3,760 tons the facility will have sacking equipment. Wyandotte Cement, Inc., was building a new bulk-storage terminal along the waterfront in Buffalo, N.Y. Hawaiian Cement Corp. completed a bulk-storage terminal at Kahului, Maui, with a capacity of 2,250 tons. A similar facility was under construction at Kawaihae, Hawaii, for completion in late 1973. An additional terminal was planned for the Island of Kauai.

Kaiser Cement & Gypsum Corp. completed a new $345,000 distribution plant at Spokane, Wash., near the site of the 1974 World's Fair. The company replaced the barge *Anchorage*, which sank late in 1971 off the coast of Alaska, with a new barge, *Permanente 272*, having a capacity of 6,000 tons. The vessel, acquired early in 1972 at a cost of $1.2 million, transported cement between Kaiser's Pacific Northwest and Alaska distribution facilities. The company purchased cement in Asia and marketed 56,000 tons in Australia and 94,000 tons in Guam, transporting it in two company-owned ships with combined capacity of 11,000 tons. Jalaprathan Cement Co. (35% owned by Kaiser) constructed a new bulk terminal on the waterfront in Thailand. In May, Kaiser Cement & Gypsum Corp. announced plans for construction of a $600,000 distribution facility at Cabras Island, Guam. Storage capacity will be 6,600 tons. In late spring, Missouri Portland Cement Co. received four bulk cement barges that were ordered in 1971 for river transport of cement to distribution terminals. A/S Norcem, Norwegian exporter to the United States, ordered four new cement bulk carriers valued at $25 million. Dundee Cement Co. was increasing its barge fleet from 34 to 44 units.

The Chicago and North Western Railroad inaugurated a "commoditrain" service to determine the economic and operating efficiency for the railroad and the customers on movement of cement during the construction season. The single-commodity trains were making five round trips a week from two cement producers in Mason City, Iowa, to distribution terminals in Burnsville, Minn., carrying more than 45,000 tons of cement.

Construction activity in Puerto Rico was affected by an island-wide transportation strike early in the year.

Despite costly shipping strikes, Hawaiian shipments increased 7%.

In the United States, trucks continued to haul most of the cement delivered to customers. However, railroads and barges transported most of the cement shipments from plants to distribution terminals. Trucks hauled 83% of the total cement shipments to customers, railroads 16%, and the remainder was transported by water. Nevertheless, waterborne transportation was becoming increasingly more important. The cost of shipping by barge was in the magnitude of 0.3 cents a ton-mile compared with 1.5 cents a ton-mile by rail and 6.0 cents a ton-mile by truck. Plants located adjacent to deep water were able to (1) receive raw materials, such as limestone from Texada Island, Canada, and aragonite from the Caribbean near the Island of Bimini; (2) import foreign clinker to supplement kiln production, such as at plants in Washington and Florida, or replace kiln production, such as at grinding plants in Michigan and Virginia; and (3) ship cement by barge or boat to domestic distribution centers and foreign countries.

More than 150 ships were in use throughout the world as bulk cement carriers excluding vessels used on rivers or inland waters only, but including ships on the Great Lakes. Only a half-dozen ships were in the 20,000-ton class or slightly larger. About 15 ships had a capacity ranging between 10,000 to 20,000 tons. In the fall of 1972, Ube Industries received the Nakaoki Maru No. 2, a 528-foot-long ship with a capacity of 20,700 deadweight tons (d.w.t.). The vessel had an unloading capacity of 2,000 tons an hour. Onada Cement Co. ordered a 21,000-ton ship for delivery in August 1973. Although the trend is toward larger ships, the cement carriers will be much smaller than the 150,000-ton ore/bulk/oil vessels now in use.

In addition to truck, rail, and barge, Inland Cement Industries Ltd. in Edmonton, Canada, shipped cement by air. Bulk cement in amounts up to 19½ tons have been loaded on L–100 and L–200 Hercules cargo aircraft.

CONSUMPTION AND USES

Shipments of cement into various States are considered to be an index of consumption. Portland cement consumption reached a record high, surpassing the 1971 record by 3%. Although consumption increased in 37 States and shipping districts, 18 had lower consumption. Spurred by an unprecedented construction boom, consumption in Florida increased over 1 million tons. Other States and shipping districts with large increases were: Texas, 627,000 tons; Georgia, 334,000 tons; New York metropolitan area, 271,000 tons; North Carolina, 265,000 tons; and western New York, 255,000 tons. The following States had shipment increases ranging between 170,000 and 225,000 tons: Virginia, Colorado, Arizona, Louisiana, and Oklahoma. Shipment increases exceeded 100,000 tons in Utah, Mississippi, Nebraska, southern California, Oregon, and Alabama. The greatest decrease in consumption was in Illinois, with a decline of 307,000 tons, followed by Missouri, 228,000 tons; northern California, 181,000 tons; eastern New York, 138,000 tons; eastern Pennsylvania, 136,000 tons; Washington, 125,000 tons; and Michigan, 118,000 tons.

Producers of ready-mix concrete were the primary customers for portland cement, receiving 64.4% of total shipments. Concrete product manufacturers used 13.8% of the cement to make concrete blocks, concrete pipes, precast, prestressed concrete, and other concrete products. Direct shipments to highway contractors amounted to 8.4% of the total cement consumed. Building materials dealers received 7.8% of the shipments; other contractors received 2.8%; Federal, State, and other government agencies purchased 0.3%; and 2.5% went for miscellaneous uses.

New construction activity, accounting for 11% of GNP, reached another record high in 1972, an increase of 13% over last year's record. Both single-unit and multi-unit housing construction reached new peaks. Nearly three-fourths of the new housing units were inside metropolitan areas. The South continued to dominate the residential boom, and Florida and California were the leading States. Commercial construction to provide facilities to serve the new residential areas advanced 6%. In sharp contrast, private nonresidential building decreased 3%. Public building construction was down 7%, highways and street construction decreased 6%, and sewer construction declined 12%. The value of public construction in constant dollars declined for the fourth straight year, and industrial construction declined for the third successive year. Water supply facilities construction increased 2%.

Despite record production and soaring imports, there was a shortage of cement in Florida and other Southern States, where producers allocated cement to customers. Fuel shortage at some plants and curtailed cement production resulting from a proliferation of environmental control regulations in general coincided with the construction boom in the Southeast to cause the tight supply situation. This was heightened by a continued demand shift to concrete products due to the rapid price increases of lumber and wood products.

PRICES

The average mill value[2] of portland cement (all types) was $20.31 a ton in 1972, an increase of $1.57 a ton. The mill value ranged from lows of $16.32 in Puerto Rico and $18.76 in Kansas to highs of $26.70 in Hawaii and $24.65 in Florida. The average mill value for gray cement increased 8% to $20.03 a ton. White cement increased $3.78 a ton to $45.31.

Price controls imposed under Phase II of the Economic Stabilization Act were of great concern to the cement industry because market conditions that caused prices to remain virtually unchanged for a decade had only recently begun to improve. However, within the constraints of the price control program in effect during 1972, many companies were able to implement limited price increases to partially offset increased costs. Price increases granted to individual companies by the Price Commission ranged up to $2.60 a ton. But in many instances part or all of the increase was ineffective because of competitive pressures from major cement producers in the market area whose prices were held down by the same rule. The Price Commission denied a request for industry wide price relief, so the PCA appealed to President Nixon to reconsider its request. In response to this appeal the Price Commission held a public hearing in Houston, Tex., October 6, 1972, with two of the six Commissioners attending. No decision was made by yearend.

The Corps of Engineers uses about 5 million tons of portland cement a year for civil works and military construction. Although the Corps does not purchase cement itself, it follows the price trend in the bids. However, the bid price is not the price quoted by the supplier, but does indicate the price situation in the industry. Examples of 1972 bid prices for a ton of cement for civil works were as follows: West Virginia $45.00 in March, up 51% from November 1971; Alabama $43.80 in June, up 74% from March 1971; Georgia $40.00 in March, up 50% from August 1970; Montana $36.00 in April, up 25% from February 1971; Colorado $32.00 in January, up 5% from November 1970; and Ohio $28.00 in February, up 9% from September 1970. Much of the cost escalation in the southeast was caused by a regional cement shortage, and bid prices anticipated higher freight charges on cement shipped from sources in other parts of the country.

According to Engineering News-Record, December bulk mill prices ranged from $20 a ton in Independence, Kans., to $31.60 a ton in Waianae, Hawaii, with $27.20 reported for Demopolis, Ala. All prices were subject to cash discounts. Bagged cement prices were $4 to $14 a ton higher than bulk prices. Base prices for portland cement in carload lots f.o.b. were reported monthly in Engineering News-Record for 20 cities in the United States. The December 1972 average for bulk cement was $25.25 a ton compared with $23.94 in December 1971. In the 20-city survey, bulk prices ranged from a low of $22 a ton in Pittsburgh, Pa., to a high of $28.20 a ton in Denver, Colo. Masonry cement averaged $30.75 a ton in December 1972 and ranged from $25.20 a ton in New York City and Minneapolis, Minn., to $41 a ton in Cleveland, Ohio.

---

[2] Mill value is the actual value of sales to customers, f.o.b. plant, less all discounts and allowances, less all freight charges to customer, less all freight charges from producing plant to distribution terminal, if any; less total cost of operating terminal, if any; less cost of paper bags and pallets.

Consumer Services Administration of the Commonwealth of Puerto Rico approved a selling price increase from $1.30 to $1.35 a bag of cement at the producers' level on December 1, 1972, and another increase of 5 cents a bag effective December 15. Because Puerto Rican Concrete Mixers Association firms negotiated contracts with customers on the basis of the first increase, the Puerto Rican Cement Co. postponed the second increase until April 1, 1973. San Juan Cement Co. increased the price 5 cents a bag on August 1, 1972.

Many producers suggest the only solution to the problem of pollution control expenditures is to increase prices for cement so that pollution control costs are spread among all who are financially or commercially interested in the utilization of the cement.

Price increases reported by most companies were not sufficient to offset rising production costs. Fuel oil, natural gas, and low-sulfur coal were all in short supply, so fuel costs increased. Power, labor, equipment, and materials costs also rose. Many companies reduced cash discounts and reduced their marketing area to lower distribution costs.

Some companies importing cement from Canada reported low profit on handling this cement compared with profits on cement imported from other countries. Cost-price escalations in foreign countries were also becoming a serious concern.

FOREIGN TRADE

Although hydraulic cement exported from the United States in 1972 declined 8% in quantity the value increased 7%. Four countries—Canada, Leeward and Windward Islands, Netherlands Antilles, and Mexico—received 80% of the 100,889 tons of cement exported to 73 countries. Exports were the lowest since 1963.

Portland cement and clinker imported from 22 countries for consumption in the United States and Puerto Rico soared to another alltime high of 4.9 million tons, surpassing the 1971 record by 59%. Imports were more than triple those of any year from 1850 through 1968. The largest increase was in Florida, where imports nearly doubled to alleviate a cement shortage caused by an unprecedented construction boom.

Clinker comprised 34% of the total imports in 1972 compared with 24% in 1971; 15% in 1970; and less than 10% each year from 1961 through 1969. An increasing number of plants were operating entirely or partially on imported clinker—two plants in Detroit, Mich., one each in Norfolk, Va., Miami, Fla., and Seattle, Wash. were among those responsible for increased clinker imports during 1972.

Canada continued to be the leading exporter, supplying 43% of the imported cement and clinker, followed by the Bahamas with 19%; Norway, 12%; the United Kingdom, 9%; Mexico, 6%; and France 5%.

On January 1, 1972, the rate of duty on white, nonstaining portland cement decreased from 1.5 cents to 1.0 cent per hundred-weight including the weight of containers, and the rate of duty for other hydraulic cement and clinker decreased from 0.4 cent per hundred weight to duty free. This was the final stage of annual rate modifications granted by the United States in the Kennedy round of trade negotiations concluded on June 30, 1967, under the General Agreement on Tariffs and Trade (GATT). The statutory import duty for countries that do not have most-favored-nation status was 8 cents per hundred-weight for white, nonstaining portland cement and 6 cents a hundred-weight for other hydraulic cement and clinker.

WORLD REVIEW

About 1,600 clinker-producing cement plants in 133 countries were in operation, with a total annual capacity of 675 million tons. In addition, more than 2,400 very small cement plants were reported operating in many municipalities in the People's Republic of China, accounting for about 40% of the country's estimated 20-million-ton capacity. Numerous new cement plants were under construction or in various stages of planning and financing in many countries. Old plants were being modernized, expanded, or replaced, not only to increase efficiency, but to meet air pollution control demands compelled by a growing concern in many nations for the quality of the environment. Production capacity growth was expected to continue.

The world cement situation continued to be a dichotomy of chronic shortage in many countries in Europe, Asia, and Latin America, while a surplus existed in other countries, such as Argentina, Canada, Italy, and the Philippines. Production costs were increasing in virtually every country. Sharp rises in fuel and power costs were reported increasing in some countries by 50% or more. Wages have increased and transportation costs were up. In many countries, prices were fixed by government regulations.

During 1972, European countries belonging to the European Cement Association (CEMBUREAU) started operating five new plants with a combined annual capacity of 2.2 million tons. In addition, 20 new kilns went into operation with a combined annual capacity of 8.8 million tons. Nine new plants and 14 plant expansions were under construction that will increase the annual clinker production capacity by 13 million tons when completed in 1973.

Abu Dhabi.—Plans were made for construction of a new cement plant at Al-Ain near the mountain of Hafeeth, with an annual capacity of 220,000 tons. Production was scheduled for late 1973.

Algeria.—Three new cement plants under construction with a total capacity of 2.3 million tons were behind schedule. Only the 550,000-ton a year plant at Hadjar-Soud near Annaba will be near completion by the end of 1973.

Angola.—Companhia dos Cimentos de Angola was expanding the Lobito plant from its present annual capacity of 99,000 tons to 220,000 tons.

Australia.—Australia Portland Cement Ltd. started using natural gas, replacing oil and coal at the Geelong plant.

Austria.—Perlmooser Zementwerke A.G. started operating a new kiln at its Rodaun plant with an annual capacity of 530,000 tons. Gmunder Portlandzementfabrik Hans Hatschek A.G. was installing a kiln at its Gmunden plant with an annual capacity increase of 290,000 tons. Completion was scheduled for 1973. Schretter and Cie. was replacing old kilns with a new kiln. When completed in 1973 the annual capacity will be increased by 290,000 tons.

Belgium.—Ciments d'Obourg S.A. was installing a new kiln at its Obourg plant with a daily capacity of 3,000 tons scheduled for operation in the spring of 1973.

Brazil.—Companhia Cimento Vale do Paraiba was installing dry-process equipment at its cement plant in Pedra do Sino, Carandaí, Minas Gerais, to increase the annual capacity by 550,000 tons. Cia. de Cimento Nacional de Minas (Ciminas), a new company formed by international investors including ITT and Holderbank, was constructing a cement plant at Pedro Leopoldo in Minas Gerais with an annual capacity of 1.1 million tons. Cimento Tocantins was constructing a plant in the Distrito Federal near Brasília with an initial annual capacity of 190,000 tons during 1972. Plans were made to increase the annual capacity to 360,000 tons by the end of 1973. Camargo Correa Industrial was completing construction of a plant at Apiaí, São Paulo, with an annual capacity of 660,000 tons. Cia. de Cimento Atol was constructing a cement plant at Santo Antonia da Barra, Alagoas. Cia. de Cimento Itambe was building a plant at Campo Largo, Paraná. Cia. Agro Industrial de Monte Alegre expected completion of its plant with an annual capacity of 100,000 tons in Monte Alegre, Pará, in 1973. Mineração e Cimento Vale do Itajai "Cimenvale" had under construction a plant at Brusque, Santa Catarina. In 1972 Cia. de Cimento Portland Gaucho started operation of its new plant in Municipio de Pinheiro Machado, Rio Grande do Sul, with an annual capacity of 238,000 tons. Cia. de Cimento Portland Mossoró planned construction of a plant at Mossoró, Rio Grande do Norte, for completion in 1974 with an annual capacity of 110,000 tons.

Cia. Ituacu de Calcáreos was constructing a plant at Ituaçu, Bahia, with an annual capacity of 120,000 tons. Cia. Nacional de Cimento Portland started construction of a plant at Cantagalo, Rio de Janeiro, with an annual capacity of 792,000 tons. Industrias de Cimento Portland Cantagalo was building a plant at Macaé, Rio de Janeiro, scheduled for completion in 1973 with an annual capacity of 950,000 tons. Itapetinga Agro-Industrial was building two plants with an annual capacity of 198,000 tons each at Lajes, Rio

Grande do Norte, and at Codó, Maranhão. Serrana S.A. de Mineração was constructing a plant near Jacupiranga, São Paulo, with an annual capacity of 440,000 tons scheduled for operation in 1973. Sociedade de Empreedimentos Industrials Commerciais et Mineração planned construction of a plant at Lagoa Santa Belo Horizonte, Minas Gerais, for completion in 1974 with an annual capacity of 1.1 million tons. Another plant was in the planning stage for Campo Formoso, Bahia.

Bulgaria.—Reconstruction of equipment at the Beli Isvor cement plant near Vratsa will increase annual capacity by 130,000 tons, to 750,000 tons. A new, fifth kiln will be installed that will increase capacity another 350,000 tons to a total of 1.1 million tons.

Cameroon.—The clinker grinding plant completed in January 1971 at Bonaberi near Douala will have its capacity doubled from the present 132,000 tons a year. The grinding plant at Figuil in the north, completed in November 1971, will increase its annual capacity to 50,000 tons.

Canada.—Ten companies continued to operate 24 plants, with a capacity of 14.9 million tons. Canada Cement Lafarge Ltd. was constructing a new plant at Bath, Ontario, with a kiln 19 feet by 22 feet in diameter by 655 long. The plant will have an annual capacity of 1.1 million tons when completed in 1973, an increase of 150,000 tons a year. The company plans to phase out its 64-year-old Belleville plant with a capacity of 770,000 tons by October 1973. The company also plans to add a new kiln, 15 feet by 17.5 feet in diameter by 490 feet long, with an annual capacity of 500,000 tons, at its St. Constant, Quebec, plant. When completed in 1974 the total capacity will be 1 million tons. Canada Cement Lafarge planned to replace two old kilns at its Exshaw, Alberta, plant with a new kiln which will increase the capacity by 200,000 tons. When completed in 1975 the total annual capacity will be 700,000 tons. The company was also modernizing its Havelock, New Brunswick, plant and will increase the capacity 100,000 tons a year.

Independent Cement Inc. installed a fourth kiln during 1972 that increased the annual capacity of its Joliette, Quebec plant 220,000 tons to a total 880,000 tons. St. Lawrence Cement Co., operating the largest suspension preheater kiln in North America at Clarkson, Ontario, was installing the largest grinding mill in the world, 18 feet in diameter by 72 feet in length. Lake Ontario Cement Ltd. will increase annual capacity at Picton 850,000 tons by the end of 1974. St. Marys Cement Ltd. at Bowmanville planned to increase the annual capacity of its plant 350,000 by year-end 1974 with the installation of a kiln 14 feet by 16 feet in diameter by 480 feet long.

Chile.—Corporación de Fomento de la Producción has obtained a majority share holding in Cemento Cerro Blanco de Polpaico and Fabrica de Cemento El Melon S.A. In December the Soviet Union agreed to assist in building a cement plant in the south.

China, People's Republic of.—The number of small cement plants in the provinces has about doubled since 1960, with about 2,400 reportedly operating in 1972. The combined output of the plants provided more than 40% of the total national production. Following is a brief summary of small cement plants in some provinces or autonomous regions: Fukien—59 plants in 48 out of a total of 66 hsien (counties) and municipalities with total output exceeding 400,000 tons; Yün-nan—about one-third of its counties have small plants; Kan-su–77 plants are located in 52% of the counties; Honan—more than 100 plants were set up mostly by counties; Chiang-Hsi—of the 125 plants in the province, 116 are run by counties and communes; Chiang-Su—93 plants in 57 counties and municipalities accounted for 50% of the total cement output of the province; Shen-hsi—107 plants operated at or above county level and more than 200 commune-operated plants; Che-Chiang—a large number of small plants operated in the majority of the counties and 6 coastal regions; Hsin-Chiang—more than 50 plants were in operation with the output accounting for 53% of the total in the region and another 30 plants were under construction; and Kwang-tung—129 small plants and 12 large plants were operating in 91 out of 107 counties and municipalities in the province. Output of the small plants accounted for 74% of the total. In Nan-Hai County, Fo-Shan region (ti chu), 27 commune-operated kilns with a combined total annual capacity of 8,000 tons were producing cement in addition to the county-operated plants.

Quality of the small plant cement production was reported at or above grade 400, which has a compressive strength about two-thirds that of type I portland cement (ASTM C–150).

Colombia.—Cementos del Caribe S.A. was installing a new kiln at its Baranquilla plant. When completed in late 1973 the daily capacity will be increased by 880 tons a day.

Costa Rica.—Calhidia S.A., a joint venture of Costa Rican and Spanish investors, received government approval for the installation of the country's second cement plant. Located at Patarrá near San Jose, the initial annual capacity will be 132,000 tons. Completion was scheduled for October 1975. Construction was started by Industria Nacional de Cemento S.A. at its Cartago plant to convert from a wet-process to dry-process kiln to raise the annual production capacity to 450,000 tons by the end of 1974.

Cyprus.—Cyprus Cement Co. Ltd. planned to install a new kiln at its Moni plant with a daily capacity of 700 tons. When completed in the spring of 1975 the annual capacity of the plant will be 350,000 tons.

Czechoslovakia.—A plant was under construction in western Slovakia that will have an annual capacity of 770,000 tons of portland cement and 100,000 tons of white and colored cement.

Dahomey.—Société des Ciments du Dahomey operated a clinker-grinding plant at Cotonou with an annual capacity of 200,000 tons. A kiln was under construction at Onigbolo near Pobe with an annual capacity of 300,000 tons.

Denmark.—Aalborg Portland Cement Co. installed a new 22.6 feet in diameter by 774 feet in length dry kiln at its Rørdal plant, and increased the daily capacity by 2,500 tons. The clinker cooler comprises 11 planetary tubes, each 65.6 feet long by 7 feet in diameter.

Dubai.—National Cement Co. Ltd. planned to start construction of a cement plant about 6 miles south of Dubai in 1973. The plant will have an annual capacity of 500,000 tons, the largest in the Persian Gulf, when completed in May 1975.

Egypt, Arab Republic of.—In October tenders were issued for equipment to expand the annual capacity of two cement plants at Torah and Alexandria nearly 1 million tons. In November Soviet Union assistance was secured to build two new plants with a combined annual capacity exceeding 1 million tons at Assyut in Upper Egypt and Helwan near Cairo. When construction of the four plants is completed the country's total capacity will rise to 4.8 million tons. A fifth plant with an annual capacity of 600,000 tons was planned for construction at Alexandria for completion by 1977.

Finland.—Lojo Kalkverk installed a new kiln with an annual capacity of 350,000 tons at its Virkby plant.

France.—On June 5, Ciments de Champagnole S.A. started operation of its new plant at Rochefort-sur-Nenon (Jura) with an annual capacity of 450,000 tons. S.A. des Ciments Vicat began operating a new kiln with a capacity of 300,000 tons.

Germany, West.—Breitenburger Portland-Cement-Fabrik had a new kiln under construction at its Lägerdorf plant with a daily capacity of 3,300 tons. Nordcement A.G. scheduled completion of its new 1-million-ton-a-year Alemannia plant at Höver for spring 1973. Bomke and Bleckmann, Dyckerhoff, Heidelberg, Solnhofer, and Wittekind each had expansion projects under construction with a combined annual capacity of 3.6 million tons.

Greece.—General Cement Co. S.A. started full production with new kiln facilities at its Olympos plant in Volos that increased annual capacity by 850,000 tons to a total of 2 million tons. The company announced plans for a third plant at Méthana, Eastern Pelopónnesus, near the Saronic Gulf, with an initial annual capacity of 1.4 million tons scheduled for 1975. Halyps Cement Co. S.A. was constructing a new kiln at its Skaramanga plant that will increase annual capacity from 460,000 tons to 900,000 tons when completed in 1973.

Hungary.—A cement plant started operation at Beremend near Siklos with an annual capacity of 1 million tons.

India.—Jaipur Udyog Ltd. started operating a plant at Beawar, Ajmer district of Rajasthan, with an initial capacity of 290,000 tons a year to be increased to 580,000 tons in 1973. The Cement Corp. of India Ltd. was constructing a plant at Kurkunta and had plans for two new plants at Bukajan, Assam, and Paonta, Himachal Pradesh, each with an annual capacity of 200,000 tons. A cement plant was reported operating in Cherrapunjee, reputed to be one of the wettest places on earth.

Indonesia.—Cibinong Cement Co. will install a single dry-process kiln with a suspension preheater at Cibinong, 30 miles south of Jakarta. The $31.5 million plant scheduled for completion by yearend 1974 will have an annual capacity of 550,000 tons. The company will construct a $3.5 million power plant to serve the new facility. Yuo Ming Co. Ltd. of Hong Kong, in a joint venture with P. T. Gunung Ngadeg Djaya, plans to build a $20 million cement plant in central Java.

Iraq.—A new plant was planned for construction at Al Fallujah, about 35 miles west of Baghdad, with an annual capacity of 200,000 tons. Another plant to be built by Polish engineers was scheduled for completion in 1974 near Baghdad with an annual capacity of 84,000 tons.

Ireland.—Cement Ltd. started operating a new kiln at Platin, west of Drogheda, with an increased annual capacity of 400,000 tons. Cement Roadstone Ltd. was constructing the country's third and largest cement plant at Platin, which was near completion at yearend.

Israel.—Israel Portland Cement Works "Nesher" Ltd., the country's sole cement producer, purchased a third plant at Bet Shemesh (halfway between Jerusalem and Tel Aviv) that has been closed. The plant will be rehabilitated for operation in May 1973. The company plans to build a fourth plant with an annual capacity of 660,000 tons for operation in 1975. By then the annual production capacity will reach 2.5 million tons. Uri Matissis and Co. planned to build a 400,000-ton-a-year plant in Mizpe Ramon, Negev, about 30 miles south of Beersheba.

Italy.—Increased production costs, government price controls, and a building recession forced seven small cement plants to close. At Guidonia, output of the new Union Cementerie Marchino Emiliane e di Augusta S.p.A. (UNICEM) new dry-process kiln with a suspension preheater has exceeded 4,400 tons of clinker a day with fuel consumption averaging 750 Kcal per kg of clinker (approximately 500,000 B.t.u. a barrel). Cementi Portorecanati S.p.A. started operating its new plant at Castelraimondo, Macerata, with an annual capacity of 440,000 tons. Cementerie di Sardegna S.p.A. was constructing a new plant at Samatzai, with an annual capacity of 440,000 tons when completed in 1973, to replace its Cagliari plant. Cementerie Calabro-Lucane S.p.A. had two plants under construction at Castrovillari, Cosenza, and Matera. When completed in 1973, each plant will have an annual capacity of 440,000 tons.

Japan.—Increased demand and strict pollution control regulations forcing the closure of some kilns were mostly responsible for a cement shortage in the country. Ube Industries, Ltd., installed a new dry-process kiln, reported to be the world's largest, at its Isa plant in Yamaguchi Prefecture. The kiln, 20.3 feet in diameter by 410 feet long, has an annual capacity of nearly 2 million tons, or approximately 230 tons an hour. The suspension preheater is 258 feet high and comprises two lines with four sets of cyclones in each line. The clinker cooler is 14.8 feet by 13.8 feet. A new 200-ton-an-hour vertical grinding mill was installed for the raw materials. Onada Cement Co. Ltd. installed a new kiln equipped with a new Reinforced Suspension Preheater (RSP) system with a daily capacity of 5,500 tons. The company planned to install a 3,000-ton-a-day kiln with the RSP system at its Ofunato plant. Sumitomo Cement Co. Ltd. installed a new kiln at its Tochigi plant with an annual capacity of 720,000 tons and new facilities with a capacity of 1.2 million tons at its Ako Nakamizuo plant in Hyogo-Ken. Nihon Cement Co. Ltd. installed a new kiln with a capacity of 1.2 million tons at its Kamiiso plant in Hokkaido.

Korea, Republic of.—Tong Yang Cement Manufacturing Co. Ltd. planned to more than double the capacity of its Samch'ŭk plant in Kang Wŏn-Do.

Kuwait.—The Kuwait cement factory was dedicated on May 15, 1972. The new plant has an annual capacity of 330,000 tons.

Lebanon.—Romania's Technochin, in a joint venture with a group of Lebanese investors, plans to build Lebanon's fourth cement plant. The plant will have a daily capacity of 880 tons and completion is scheduled for late 1973.

Libya.—Libyan Cement Co. started expanding the capacity of its plant in the

Hawari area near Benghazi. The new plant, started in 1972 with an annual capacity of 220,000 tons, will have an additional capacity of 440,000 tons when completed in 1974. National Cement Co. had under construction an expansion of its plant at Homs to increase the annual capacity from 110,000 tons to 440,000 tons, with completion scheduled for mid 1974.

Malaysia.—Cement Industries of Malaysia Sdn. Berhad was constructing a plant in Perlis with an annual capacity of 400,000 tons. Production was scheduled for October 1974.

Mexico.—By 1972 all cement companies required a minimum of 51% Mexican ownership to comply with a 1970 government decree involving Mexicanization of basic industries. General Portland Cement Co. was negotiating for 49% interest in the Tamuin plant owned by Cementos Anahuac del Golfo S.A. The company had a contract to purchase cement for delivery in the southeastern United States through 1974. Cementos Anáhuac was expanding combined daily production capacity from 5,800 to 8,000 tons. Cementos Guadalajara, S.A. merged with Cementos California S.A. and planned to build a new plant at Culiacán, Sinaloa, with a daily capacity of 1,200 tons. Cementos Veracruz S.A. planned to increase the annual capacity of its Orizaba, Veracruz, plant from 275,000 to 660,000 tons while removing obsolete kilns with a combined 100,000-ton capacity. Completion was scheduled for late 1974. Cementos Atoyac S.A. planned to double the daily capacity of its Puebla plant, from 440 to 880 tons. Cementos de Sinaloa, S.A. was expanding the daily capacity of its Los Hornillos plant from 440 to 1,320 tons. Cementos plant from 440 to 1,320 tons. Cementos Apasco S.A. was constructing a new preheater kiln with a daily capacity of 2,000 tons at its Apaxco plant. The kiln was scheduled for operation in late 1974.

The following companies completed plant expansions in 1972 with the daily capacity increases in parentheses: Cementos Acapulco at Acapulco (330); Cementos Anáhuac at Barrientos (2,000); Cementos Chihuahua at Cuidad Juárez (390); Cementos Maya at Mérida (550); Cementos Mexicanos S.A. at Monterrey (1,300) and at Torreón (550); and Cementos La Cruz Azul at Lagunas (990). Expansions under construction for completion in 1973 were: Cementos Anáhuac at Barrientos (2,200); Cementos La Cruz Azul at Cuidad Cruz Azul (770); and Cementos Tolteca S.A. at Atotonilco (2,200).

Morocco.—The Moroccan and Algerian Governments have signed an agreement for the formation of a jointly-owned company to build and operate a cement plant at Oujda, Morocco, near the Algerian border. The annual capacity of the plant will be 1 million tons.

Mozambique.—On June 30, 1972, Companhia de Cementos de Moçambique S.A.R.L. inaugurated the third kiln at the Nova Maceira plant at Dondo near Beira with an added annual capacity of 330,000 tons, bringing the plant's total to 506,000 tons. The fourth kiln was under construction at the company's Matola plant near Lourenço Marques with an annual capacity of 660,000 tons. Completion was scheduled for late 1977.

Nigeria.—Calabar Cement Co., Ltd. plans to increase the annual capacity of its plant at Calabar from 110,000 to 330,000 tons.

Okinawa.—Ryukyu Cement Co., Ltd. planned to increase the annual capacity of its plant at Yabu 15% from the present 450,000 tons; completion is scheduled for 1973. Niho Cement Co. of Japan acquired a 10% interest in Ryukyu Cement Co., while Kaiser Cement & Gypsum Corp.'s interest was reduced to 46%.

Panamá.—Importation of more than a million sacks of cement was not enough to meet the country's demand. Cemento Atlantico S.A. was installing a new kiln with a preheater at its Colon plant that will increase the annual capacity of the plant from 110,000 to 330,000 tons. Completion was scheduled for 1974.

Paraguay.—Plans were announced to double the capacity of Industria Nacional del Cemento's plant at Puerto Vallemi from 110,000 to 220,000 tons.

Peru.—Cementos Lima S.A. replaced eight old kilns at its Atacongo plant with one kiln equipped with a suspension preheater. The kiln has a daily capacity of 2,700 tons, an increase of 900 tons per day.

Philippines.—Production was only 48% of the 6.6 million tons capacity in 1972. The Development Bank of the Philippines foreclosed on two cement plants. Floro Cement Corp.'s new plant at Lugait, Misamis Oriental and Mindanao Portland Cement Corp.'s plant at Iligan, Lanao did not operate during the year. In 1972 Prime White Cement Corp. became the first company to produce white cement in the Philippines. The annual capacity of the new plant at Asturias, Cebu was 33,000 tons, adequate to meet the country's demand.

Poland.—Two new plants were under construction at Opole and Kielce, each with a daily capacity of 3,500 tons.

Portugal.—Companhia Cimento Tejo was installing two new wet-process kilns at its plant at Alhandra that will increase annual capacity from 858,000 to 1,540,000 tons. Completion was scheduled for 1973. Five Lille-Cail of Paris, France, has a contract to install a dry-process kiln 15 feet in diameter by 230 feet long with a multicyclone preheater for the new plant of Cía. de Cimentos do Norte at Souselas in northern Portugal. When completed early in 1974 the plant will produce 1,760 tons a day of clinker. Cía. Industrial do Cimento do Sul was constructing a new plant at Loulé in the Faro district. When completed in 1973 the annual capacity will be 330,000 tons.

Rwanda.—Plans for a cement plant at Mibirizi were included in a United Nations Industrial Development Organization (UNIDO) report. Also the People's Republic of China was reported to have an agreement to build a cement plant in the Cyangugu area.

Saudi Arabia.—Arabian Cement Co. was doubling the annual capacity of its Jidda plant to 660,000 tons. Completion was scheduled for mid-1974. The Riyadh plant of the Yamama Saudi Cement Co. was brought into operation during 1972.

Senegal.—The capacity of the Société Ouest Africaine des Ciments (SOCOCIM) plant at Rufisque will be increased by 100,000 tons to 400,000 tons a year by the end of 1973.

Somalia.—Somalia Cement Co. planned to build a plant with an annual capacity of 110,000 tons near Berbera with North Korean assistance.

South Africa, Republic of.—Cape Portland Cement Co. Ltd. had under construction the company's largest kiln at its De Hoek plant. The annual capacity will be 500,000 tons.

Spain.—American Cement Corp. signed an agreement to sell its 67% interest in Portland de Mallorca, S.A. to Cementos del Mar S.A. Cementos del Cantábrico started operating its new plant at Aboño, Carreño with an annual capacity of 720,000 tons. Cementos Alba S.A. was constructing a new plant at Jerez, Cadiz. When completed in 1973, the annual capacity will be 720,000 tons. Portland Valderrivas S.A. had a new plant under construction with an annual capacity of 880,000 tons when completed in 1973.

Sri Lanka (formerly Ceylon).—Ceylon Cement Corp. was installing a second kiln at the Puttalan plant to double the annual capacity to 484,000 tons. When completed in 1973 the country's total capacity will be 787,000 tons a year.

Switzerland.—Cementfabrik Holderbank planned to start construction in 1973 of a new plant at Rekingen, Aargau, with an annual capacity of 700,000 tons. Completion was scheduled for 1975. Société des Chaux et Ciments de la Suisse Romande planned installation of a new third kiln at its Eclépens plant with a daily capacity of 1,500 tons. The kiln will replace two smaller units when completed by mid-1974. Bündner Cementwerke A.G. was installing a new kiln at its Untervaz plant that was expected to be in operation by early 1974.

Taiwan.—Chia Hsin Cement Corp. was doubling the capacity of its Kangshan plant, with completion scheduled for early 1975. Cheng Tai Cement Corp. planned to increase the capacity of its Tsoying plant in Kaohsiung with the addition of a 1,100-ton-a-day dry-process kiln.

Thailand.—The country's cement industry capacity increased from 3,163,000 tons in 1971 to 4,455,000 tons in 1972. Siam Cement Co., Ltd. completed the first full year of production at its new plant in Kaeng Khoi, Saraburi. The plant, with an annual capacity of 825,000 tons, increased the company's total to 3.1 million tons. The company planned to install another kiln equipped with a suspension preheater and having a daily capacity of 2,500 tons at the Kaeng Khoi plant. Siam City Cement Co. started production at its new plant with an annual capacity of 660,000 tons in Saraburi, about 129 kilometers north of Bangkok.

Turkey.—Askale Tesis Müdürlugu was

operating its new plant at Erzurum with an annual capacity of 390,000 tons. The following plants were under construction with completion scheduled for 1974: Bolu Cimento Sanayii A.S. at Bolu with an annual capacity of 550,000 tons; Göltas Cimento A.S. at Isparta (620,000 tons); Mardin Cimento at Mardin (580,000 tons); and Ünye Cimento at Ünye (620,000 tons).

United Kingdom.—Rugby Portland Cement Co. Ltd. was doubling the annual capacity of its plant in Halling, Rochester, Kent, from 400,000 to 800,000 tons. The company was also doubling the capacity of its South Ferriby, Lincolnshire, plant from 390,000 to 779,000 tons. Both plants were scheduled for completion in 1974. Associated Portland Cement Manufacturers Ltd. closed its plants in Greenhithe, Kent; Harbury, Warwickshire; Dunstable, Bedfordshire; and Stone, Kent.

Zaire.—Société des Ciments du Zaire planned to increase the annual capacity of its Lukala plant from 308,000 tons to 660,000 tons. Cimenterie Nationale was constructing a new cement plant at Kimpese with an annual capacity of 330,000 tons. Completion was scheduled for May 1974. An abandoned clinker-grinding plant at Kisangari with a capacity of 198,000 tons a year was being rehabilitated for operation in early 1973.

Zambia.—Chilanga Cement Co. Ltd. was doubling the capacity of its plant at Ndola with the addition of a second dry-process kiln equipped with a suspension preheater and planetary cooler, having a daily capacity of 600 tons. When completed in 1973, the total annual capacity of the plant will be 440,000 tons.

TECHNOLOGY

Several cement producers and equipment manufacturers consider the optimum-size kiln to have a capacity of about 3,300 tons a day. Nevertheless, to fully exploit the economic advantages of mass production some companies were increasing the size of new production units incorporating the latest technology. For many years most of the significant advances in cement production technology were made and tested in Europe and Japan and slowly adopted in the United States. Recent improvements on preheater systems developed in Japan have increased kiln output tremendously and may be the most significant advance in cement technology since the preheater system was introduced.

Shortages of natural gas, fuel oil, and low sulfur coal contributed to a sharp increase in fuel costs for making clinker. Fuel costs amounting to $2.65 a ton of clinker produced in the U.S. were expected to increase and perhaps double in a few years. For this reason more companies were investigating the economics of short kilns equipped with preheaters and, in particular, suspension preheaters. Because of the more effective heat transfer in the preheater system, fuel consumption is greatly reduced in the kiln. In the first 8 months of 1972, 25% of the new kilns sold in the U.S. and Canada were equipped with suspension preheaters, accounting for 35% of the new capacity. A recently installed short kiln with a suspension preheater was producing clinker at nearly 1 million B.t.u. a ton less than long dry kilns operating alongside the new unit. This was about one-half the B.t.u. requirements for long wet kilns.

Development of continuous bypass systems to remove and control alkali content in both traveling grate and suspension type preheaters were significant technological advances that made the preheater kiln more attractive to companies in the United States. More than 450 kilns equipped with preheaters were in operation throughout the world. In 1972, Ube Industries, Ltd., installed a new kiln 20.3 feet in diameter by 410 feet long equipped with a four-stage suspension preheater. This was reported to have the world's largest kiln output with a daily capacity of 5,665 tons.

Other advantages of suspension preheater kilns in addition to lower fuel consumption are shorter material retention time, enabling use of a shorter kiln with a smaller diameter; less heat loss by radiation; and lower capital cost for installation.

Three Japanese firms developed special burners to facilitate calcination of raw materials in the suspension preheater which further increased kiln production capacity by 25% to 50%. Mitsubishi Cement Co., Ltd. received patents for calcining equipment with a fluidized bed called Mitsubishi Fluidized Calcinator (MFC). This unit comprises a separate heat source between the kiln and suspension preheater. Heat consumption of the whole clinker-producing operation including the MFC was 792 Kcal per kg of clinker, about the same as for an ordinary kiln with a suspension preheater. Power consumption using the MFC increased 0.7 kilowatt hours per ton of clinker. Very few kiln upsets occur with the use of MFC, thereby enabling a stabilized operation that increases refractory brick life and, as a result, permits continuous operation for more than 1 year with increased production capacity attained. Using the MFC, old, small kilns can be remodeled to high productivity at a relatively small construction cost.

Onada Cement Co., Ltd., and Kawasaki Heavy Industries, Ltd., jointly developed a two-chamber furnace installed in the suspension preheater structure that greatly increased clinker production capacity and heat efficiency of a kiln. The system, called Reinforced Suspension Preheater (RSP), utilizes a swirl burner and a swirl calciner to increase the decarbonation rate, which is normally 40% in suspension preheaters, to 85% to 90%. The swirling raw meal inside the furnace permits rapid heat transfer. In August 1972, installation of the RSP on the No. 3 kiln at the company's Tahara plant nearly tripled production capacity. Heat consumption for this kiln was estimated to be 760 Kcal per kg of clinker with very small heat loss. To prevent brick problems in large-diameter kilns, the diameter should be limited to 16 to 18 feet. Using the RSP system, this size kiln can produce 6,600 to 8,800 tons of clinker a day. Long continuous kiln operation is possible because of increased refractory brick life. Air pollution control problems are also reduced. The RSP can be used to increase capacity of small, old kilns.

Ishikawajima Harima Heavy Industries Co. and Chichibu Cement Co., Ltd., introduced a flash furnace with special burners to facilitate calcination in the suspension preheater. A kiln, 12.5 feet in diameter by 166 feet long, using the new furnace produced 2,200 tons a day, about twice the amount expected from this size kiln.

Harbison-Walker Refractories patented Trefoils have been in use in numerous kilns for manufacturing lime. Only recently the Trefoil was installed in a wet-process cement plant in Texas and a dry-process kiln in Virginia. The Trefoil is a supplementary heat exchanger near the firing zone of a kiln, built of refractory bricks with shapes arranged to divide the cross-sectional area of the kiln into three equal parts. By dividing the kiln load, more load surface is exposed to direct heat transfer. A fuel savings of 5% to 15% was reported. A slight increase in production occurred because of less dust loss.

To facilitate better heat exchange, one company replaced an old chain system in a kiln with a new chain system and thereby increased the production capacity of the kiln 17% while decreasing fuel consumption 17%.

Where alkali was not a problem some companies were insufflating dust collected in electrostatic precipitators. Dust recovered and pumped to the kiln ranged from 50 to more than 100 tons per day.

European-designed impactor crushers were becoming more widely accepted in the United States, along with the preheater kilns. Increased use of preheater kilns led to new developments in raw material processing. The impactor crusher was amenable to special design in permitting crushing and drying to take place simultaneously utilizing hot exit kiln gases. Raw materials with initial moisture content up to 25% have been effectively processed. Preprocessing in a crusher/dryer may account for a 3% to 15% increase in raw grinding capacity and power consumption reduction by 10% to 15%. An impactor crusher with a capacity of 1,000 tons an hour was installed recently in a western State. Mobile primary crushers were also receiving more consideration.

Roller mills were in competition with ball mills and rodmills for grinding raw materials. Two Loesche roller mills were installed at the Isa plant of the Ube Cement Co. along with the largest kiln in the world. The four-roller mill utilizes hot waste gases from the suspension preheater to dry raw materials from 5% moisture to 0.3%. Each vertical mill has the capacity to grind 230 tons an hour with 90% of the raw meal passing 200 mesh. The mills were driven by 1,500-kw motors each. To sweep the mill a fan with a 1,600-hp motor delivered 250,000 cubic meters of air an hour. Roller mills with a 450-ton-an-hour capacity each were being designed for raw grinding. Because of the limited retention time in ball mills and rodmills, kiln gas is not hot enough to dry raw materials with initial moisture content exceeding 7%. The roller mills dry effectively with kiln exit gas material with 10% to 12% moisture and material with 25% to 28% moisture using an auxiliary heating unit. Depending on the diameter of the rolls, feed size up to 6 inches can be fed to the roller mill. Although the capital cost was about 10% to 15% higher than for a ball mill or rodmill and the installation cost was about the same, the roller mill takes up less space, requires less horsepower, and operates much more quietly.

Lone Star Industries developed a new comminution process for minerals known as the Snyder process. The revolutionary new process utilizes pressure chambers and a fast valve actuator (less than 15 milliseconds) to generate shock phenomena that shatter the rock almost instantaneously, taking advantage of a mineral characteristic of the rock, which is weaker in tension than in compression. The sonic and other shock waves created in the system produce cleavage of the component minerals through internal stress at their natural grain boundaries. This contrasts with the lower efficiency of conventional grinding mills that must overcome the rock's greater compressive strength. Only a prototype installation has been in operation, with a capacity of 10 tons an hour.

A 15.5-foot-diameter by 21-foot-long raw mill powered by a 3,000-hp motor was installed in Arizona. This was the largest diameter-diaphragm ball mill supplied to the cement industry by the manufacturer.

Ball mills continue to be the most important finish-grinding mills. The trend toward larger units persists. Two mills, 16.5 feet in diameter by 54 feet long, with a capacity of 200 tons an hour each, were installed by UNICEM at its plant in Guidonia, Italy. These were gearless, variable-speed motor-driven ball mills rated at 6,000 kw. The cement fines were controlled by automatic on-line permeabilimeters. The world's largest ball mill was under construction at the St. Lawrence Cement Co. plant in Clarkson, Ontario. The 8,700-hp gearless motor, with an 18-foot-diameter by 73-foot-long mill as the rotor, has a stator 32 feet in diameter. The mill was expected to operate in mid-1973.

Many European ball mills use classifying liners, which are reported to increase grinding efficiency from 10% to 25%. The segregating liners produce self-segregation of the ball charge in the second compartment so the larger diameter balls grind the coarser material. This improved grinding efficiency decreases the circulating load, which in turn increases the separator efficiency. High-chromium grinding media used with the segregating liners reduce wear rate and deformation problems. Several domestic producers ordered the new liners for finish-grinding mills.

Sumitomo Cement Co., Ltd., developed a monitoring device for controlling the mill feed rate. Operation was based on measuring the pressure differential of air flow between the inlet and outlet of the mill. Polysius A.G., Neubeckum, West Germany, developed a continuous automatic device for determining grinding fineness. The extremely fine particles of the ground mixture are scanned by a thin needle. A piezoelectric system converts needle oscillations into electric currents that are proportional to the fineness. The method makes it possible to accurately and rapidly monitor, control, and adjust the grinding operation on the basis of the product fineness.

General Portland, Inc. research laboratories developed an expansive cement that does not depend upon sulfo-aluminates to control shrinkage in concrete. The company claims the product has more uniform expansive and stressing properties, works better under hot weather conditions, and has strengths equal to or better than type I cement. Using essentially the same raw materials and requiring only minor plant modification, the new expansive cement was expected to be produced commercially by mid-1973.

Utilizing waste fly ash produced at powerplants, Dundee Cement Co. introduced portland pozzolan (type IP) cement at its plants in Clarksville, Mo., and Dundee, Mich., and Santee Portland Cement Co.

started to intergrind fly ash to produce type IP cement at its Holly Hill, S.C., plant. The Bureau of Mines conducted studies at its Tuscaloosa Metallurgy Research Laboratory in Alabama to investigate use for two solid waste materials, fly ash and calcium silicofluoride. Research led to the development of a regulated set cement comparable to commercial products by using limestone, kaolin, fly ash, and calcium silicofluoride. Strengths equivalent to those of commercial cement were achieved with the same setting times. A report was in preparation.

Table 2.–Finished portland cement produced, shipped, and in stock in the United States,[1] by district [2]

District	Plants active during year		Production [3] (thousand short tons)		Shipments						Stocks at mills December 31 (thousand short tons)	
					1971			1972				
						Value			Value			
	1971	1972	1971	1972	Thousand short tons	Total (thousands)	Average per short ton	Thousand short tons	Total (thousands)	Average per short ton	1971	1972

r Revised. NA Not available.

[1] Includes Puerto Rico.

[2] Includes data for six grinding plants: Michigan (2) includes data for Superior, Wisc.; Pennsylvania (2); and one each in Wisconsin, California (1971), and Virginia (1972). Eight white cement facilities: Texas (3); Pennsylvania (2); one each in California, Florida, and Wisconsin; and two plants in Michigan which were phased out in 1972.

[3] Includes cement produced from imported clinker.

[4] Data may not add to totals shown, because of independent rounding.

[5] Cement imported and distributed by domestic producers only. Source of imports withheld to avoid disclosing individual company confidential data.

Table 3.—Portland cement shipped by plants in the United States, by type [1]

(Thousand short tons and thousand dollars)

Type	1971			1972		
	Quantity	Value	Average per ton	Quantity	Value	Average per ton
General use and moderate heat (types I and II)	73,703	1,362,997	$18.49	75,452	1,512,214	$20.04
High-early-strength (type III)	2,691	54,214	20.15	2,827	61,508	21.76
Sulfate-resisting (type V)	545	10,890	19.98	581	11,672	20.09
Oil-well	634	13,220	20.85	671	14,626	21.80
White	414	17,194	41.53	459	20,795	45.31
Portland-slag and portland pozzolan	104	2,068	19.88	438	8,412	19.21
Expansive	211	5,354	25.37	177	5,213	29.45
Miscellaneous [2]	702	14,760	21.03	827	19,341	23.39
Total or average [3]	79,005	1,480,696	18.74	81,432	1,653,779	20.31

[1] Includes Puerto Rico.

[2] Includes type IV, waterproof cements.

[3] Data may not add to totals shown because of independent rounding.

W Withheld to avoid disclosure of individual company confidential data; included with "Foreign countries."

[1] Includes imported cement shipped by domestic producers (1971–1972) and Canadian cement manufacturers and other importers (1972).

[2] Excludes cement used in the manufacture of prepared masonry cement.

[3] Has no cement producing plants.

[4] Less than ½ unit.

[5] Direct shipments by producers to foreign countries, U.S. possessions and territories, and also including States indicated by symbol W.

[6] Includes cement produced from imported clinker by domestic producers.

[7] Includes imported cement distributed by domestic producers (1971–72), Canadian cement manufacturers and other importers (1972). Origin of imports withheld to avoid disclosing individual company confidential data.

Table 5.—Clinker capacity and production in the United States,[1] by district, as of December 31, 1972

	Active plants[2]			Number of kilns	Daily capacity (thousand short tons)	Average number of days for maintenance	Apparent[3] annual capacity (thousand short tons)	Production[4] (thousand short tons)	Percent utilized

Total or average	106	63	169	461	256	31	85,399	77,378	90.6

[1] Includes Puerto Rico.

[2] Includes white cement manufacturing facilities. Lone Star Industries Inc. ceased clinker production at its Norfolk, Va., plant in April 1972.

[3] Calculated on individual company data: (365 days, minus average days for maintenance, times the reported 24 hour capacity.)

[4] Includes production reported for plants which added or shut down kilns during the year.

Table 6.—Raw materials used in producing portland cement in the United States[1]

(Thousand short tons)

Raw materials	1970	1971	1972
Cement rock	22,824	23,074	23,799
Limestone (including oystershell and aragonite (1972))	83,230	85,857	90,003
Marl	1,669	1,741	2,080
Clay and shale[2]	11,833	11,808	12,158
Blast-furnace slag	853	713	759
Gypsum	3,491	3,750	4,094
Sand and sandstone (including silica and quartz)	2,193	2,226	2,774
Iron materials[3]	777	693	839
Miscellaneous[4]	341	479	414
Total	127,211	130,341	136,920

[1] Includes Puerto Rico.

[2] Includes fuller's earth, diaspore clay, and kaolin.

[3] Includes iron ore, pyrite cinders, and mill scale.

[4] Includes fluorspar, pumicite, calcium chloride, soda ash, borax, staurolite, fly ash, bauxite, diatomite, air-entraining compounds, and grinding aids.

Table 7.—Clinker produced and fuel consumed by the portland cement industry in the United States by process [1]

Year and process	Clinker produced			Fuel consumed		
	Plants active during year	Thousand short tons	Percent of total	Coal (thousand short tons)	Oil (thousand 42-gallon barrels)	Natural gas (thousand cubic feet)
1971:						
Wet	107	45,015	59.8	4,072	8,155	145,888,563
Dry	63	30,216	40.2	3,110	2,599	74,084,672
Total	170	75,231	100.0	7,182	10,754	219,973,235
1972:						
Wet	107	45,846	59.2	4,158	8,898	147,540,429
Dry	63	31,532	40.8	3,181	3,333	75,810,093
Total	170	77,378	100.0	7,339	12,231	223,350,522

[1] Includes Puerto Rico.

Table 8.—Clinker produced in the United States, by kind of fuel [1]

Year and fuel	Clinker produced			Fuel consumed		
	Plants	Thousand short tons	Percent of total	Coal (thousand short tons)	Oil (thousand 42-gallon barrels)	Natural gas (thousand cubic feet)
1971:						
Coal	40	[2]15,773	21.0	4,026	XX	XX

Unspecified[2]	--	--	--	--	44	12	56
Total	17,868	342	18,883	867	53,297	5,958	[3]79,005
1972:							
Railroad	9,020	295	835	213	11,126	714	12,888
Truck	516	60	17,940	848	43,278	5,253	67,319
Barge and boat	8,426	5	312	--	843	--	1,155
Unspecified[2]	--	--	--	--	63	7	70
Total	17,962	360	19,087	1,061	55,310	5,974	[3]81,432

[1] Includes Puerto Rico.

[2] Includes cement used at plant.

[3] Bulk shipments were 91.4% (72,180 tons); container (bag) shipments were 8.6% (6,825 tons) for 1971. Bulk shipments were 91.4% (74,397 tons); container (bag) shipments were 8.6% (7,035 tons) for 1972.

NA Not available.

[1] Source: 1818–1923 U.S. Geological Survey; 1924–1972 U.S. Bureau of Mines. Includes Puerto Rico (1939–1972); Hawaii (1945–1946) (1960–1972).

[2] The data for 1890 and previous years were estimates made at the close of each year and are believed to be substantially correct. Since 1890 the data are based on returns from all producers.

[3] Quantity in units of thousand short tons.

[4] Data prior to 1955 not comparable due to changes in tabulating procedures by the Department of Commerce.

[5] Capacity based on production of finished portland cement (1908–1969); clinker (1970–1972). Clinker capacity calculated on individual company data; (365 days, minus average days for maintenance, times the reported 24 hour kiln capacity).

[6] Data up to and including 1911 are for production. Shipment data not collected before 1912.

[7] Does not include portland cement used in making masonry cement (1955–1972).

[8] Includes cement imported by domestic producers (1966–1972).

[9] Separate data for natural and pozzolan cements are available for the years 1896–1915. Pozzolan cement not included prior to 1896.

[10] The term "Masonry Cement" was first introduced in 1922 and data were included with natural cements.

[11] Separate production and shipment data for masonry cement were collected for the first time in 1955. These data include masonry cement from all domestic portland, natural, and slag cement manufacturers.

[12] Excludes natural and pozzolan cement (1970–1972).

[13] Data may not add to totals shown because of independent rounding.

[14] Production data not collected before 1925. Data for prior years represent shipments.

[15] Calculated prior to rounding.

[16] Less than ½ unit.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Because this table contains data in thousand short tons rather than thousand 376-pound barrels (as in previous editions of this chapter), revisions have not been individually indicated in the 1970 column.

[2] Year beginning March 21 of that stated.

Chromium

By John L. Morning[1]

Technologic change in the manufacture of stainless steel during the past several years brought about increasing use of lower cost high-carbon ferrochromium in place of higher cost low-carbon ferrochromium. Although the domestic chromium alloy producers maintained their production pace of the previous year, increasing demand for chromium alloys was met by imports, which rose to a record high of 141,000 tons.

Table 1.—Salient chromite statistics

(Thousand short tons)

	1968	1969	1970	1971	1972
United States:					
Exports	13	49	41	35	20

Stocks Dec. 31: Consumer	912	675	733	1,019	857
World: Production	5,444	5,865	6,672	6,908	6,841

Legislation and Government Programs.—An amendment to Public Law 92–156 (section 503) allowed the importation of strategic and critical materials from Southern Rhodesia in 1972, and the Department of Treasury published regulations removing controls on these materials.[2] Various congressional efforts were made during the year to nullify section 503, but both the House and Senate rejected plans to reinstall the embargo. A Federal suit by some congressional members to reinstate the embargo was rejected by the court.

Government chromium stockpile material inventories and objectives are shown in table 2. Included in the inventories is material sold but unshipped. This includes chemical-grade chromite, 341,680 tons; metallurgical-grade chromite, 116,906 tons; and refractory-grade chromite, 6,772 tons.

General Services Administration (GSA) under various disposal programs offered for sale all three grades of chromite either by competitive bidding or by negotiated sales. Sales were as follows: Chemical-grade chromite, 1,796 tons, and refractory-grade

Table 2.—U.S. Government chromium stockpile material inventories and objectives

(Thousand short tons)

	Objective	Inventory by program, Dec. 31, 1972			
		National stockpile	Defense Production Act	Supplemental stockpile	Total
Chromite, chemical-grade	250	544	--	366	910
Chromite, refractory-grade	368	991	--	178	1,169
Chromite, metallurgical-grade	2,911	332	901	323	1,556

Chromium metal	4	1	--	7	8

---

[1] Supervisory physical scientist, Division of Ferrous Metals.

[2] Federal Register. V. 37, No. 16, Jan. 25, 1972.

chromite, 13,618 tons. Actual deliveries of chromite from government stockpiles from current or prior sales contracts were: Chemical-grade, 116,128 tons; metallurgical-grade, 53,366 tons; and refractory-grade, 14,416 tons.

A 1964 finding that chromic acid from Australia was sold at less than fair value within the meaning of the Antidumping Act, 1921, as amended, was revoked in 1972 by the Department of Treasury.[3]

DOMESTIC PRODUCTION

Domestic mine production of chromite ceased in 1961 when the last Government Defense Production Act contract was phased out. However, the United States continued to be one of the world's leading chromite consumers in producing chromium alloys, refractories, and chemicals. The principal producers of these products were as follows:

Company	Plant
Metallurgical industry:	
Airco Alloys and Carbide Div., Air Reduction Co. Inc	Calvert City, Ky.
	Niagara Falls, N.Y.
	Charleston, S.C.
Chromium Mining and Smelting Corp	Woodstock, Tenn.
Foote Mineral Co	Vancoram, Ohio
	Graham, W.Va.
Interlake Inc	Beverly, Ohio
Ohio Ferro-Alloys Corp	Brilliant, Ohio
Shieldalloy Corp	Newfield, N.J.
Union Carbide Corp	Niagara Falls, N.Y.
	Marietta, Ohio
Refractory industry:	
The Babcock & Wilcox Co	Augusta, Ga.
Basic, Inc	Maple Grove, Ohio
Corhart Refractories Co., Inc	Buckhannon, W.Va.
	Louisville, Ky.
E. J. Lavino & Co. (Div. of IMC)	Newark, Calif.
	Plymouth Meeting, Pa.
General Refractories Co	Baltimore, Md.
	Lehi, Utah
Harbison-Walker Refractories Co. (Div. of Dresser Industries, Inc.)	Hammond, Ind.
	Baltimore, Md.
Kaiser Aluminum & Chemical Corp	Moss Landing, Calif.
	Columbiana, Ohio
North American Refractories Co	Womelsdorf, Pa.
Ohio Fire Brick Co	Jackson, Ohio
Chemical industry:	
Allied Chemical Corp	Baltimore, Md.
Diamond Shamrock Corp	Castle Haynes, N.C.
	Kearny, N.J.
PPG Industries, Inc	Corpus Christi, Tex.

Foote Mineral Co. announced at yearend that it would stop ferrochromium production at its Vancoram, Ohio, plant. Anticipated pollution control costs connected with the operation together with writeoff costs made the action necessary, according to Foote.

Diamond Shamrock Corp. dedicated its new chromium chemicals plant at Castle Haynes, N.C., which began operation late in 1971. Reportedly the plant will process South African chromite.

A worldwide survey on chromium supply and demand was published early in the year.[4] This study presented information on supply and demand as well as worldwide trade by principal countries.

CONSUMPTION AND USES

Domestic consumption of 1,140,000 tons of chromite ore and concentrate containing about 353,000 tons of chromium was 4% higher than in 1971. Of the total chromite consumed, the metallurgical industry used 63.8%, the refractory industry 19.6%, and the chemical industry 16.6%. The metallurgical industry consumed 727,000 tons containing 238,000 tons of chromium in producing 350,000 tons of chromium alloys and chromium metal. About 68.7% of the metallurgical-grade ore had a chromium-to-iron ratio of 3:1 and over; 18.5% had a ratio between 2:1 and 3:1; and 12.8% had a ratio of less than 2:1.

[4] Roskill Information Services Ltd. Chromium Minerals, Ferrochrome, Chromium and Chromium Chemicals: World Survey of Production and Consumption With Special Reference to Future Demand and Prices. London, January 1972, 236 pp.

Producers of chromite-bearing refractories consumed 224,000 tons of ore containing 55,000 tons of chromium. The chemical industry consumed 189,000 tons of chromite containing 59,000 tons of chromium in producing 147,000 tons of chemicals (sodium bichromate equivalent).

The technologic change in manufacturing stainless steel, that of decarburizing a molten bath by one of several processes, was reflected in both production and consumption of chromium alloys. Domestic producers switched their product mix to a higher proportion of lower cost high-carbon ferrochromium to meet consumer demand. Consumers in 1971 used about equal quantities of high-carbon and low-carbon ferrochromium; whereas in 1972 the ratio was 1.5:1.

Chromium has a wide range of applications in the metallurgical industry. Its principal use is in stainless and heat-resisting steels, but its use in alloy and tool steels, cast iron, nonferrous alloys, and welding and alloy hard facings rods and materials accounted for 30% of chromium alloy consumption.

The refractory industry used chromium in the form of chromite, primarily for manufacture of refractory bricks for use in metallurgical furnaces and ladles. Some chromite, however, is employed for refractory purposes in mortars and in ramming, castable and gunning mixes, or directly for furnace repair.

The chemical industry consumes chromite for manufacture of sodium or potassium dichromate, the base material for a wide range of chromium chemicals used in electroplating, pigments, leather processing,

[3] Includes 549 tons of chromium metal.

metal treatment, catalysts, and other applications.

The proposed Highway Safety Act of 1973 could lead to significantly increased use of chrome yellow paint for marking the Nation's highways. Chrome yellow (lead chromate) not only has high visibility, but also has good resistance to degradation by light and resistance to chemicals used to remove snow and ice from pavements. Chrome yellow contains a nominal 16% chromium.

STOCKS

Chromite stocks dropped significantly during the year as all three consuming industries reduced their inventories. Stocks decreased 10% in the metallurgical industry, 31% in the refractory industry, and 19% in the chemical industry compared with 1971 totals. Combined producer and consumer stocks of chromium alloys increased nearly 9%.

Stocks of chromium chemicals (sodium bichromate equivalent) at producer plants decreased from 14,271 tons in 1971 to 13,936 tons in 1972.

Total	912	740	733	1,019	857

PRICES

Reversing the past 5-year trend, the published price for Soviet-metallurgical-grade chromite for 1972 delivery was 13 to 15% lower than in 1971. Based on 48% Cr_2O_3, 4:1 chromium-to-iron ratio, f.o.b. Russian ports, the price was quoted at $45.00 to $46.50 per metric ton. An adequate stock level and lower demand for chromite as a result of the high level of ferrochromium imports were responsible for the lower price quotation. Published price for Turkish chromite 48% Cr_2O_3, 3:1 ratio, per long ton, delivered Atlantic ports was $55 to $56; unchanged from the 1971 price. However, industry sources indicated that Turkish chromite was priced at $43 to $47 per long ton. South African Transvaal chromite 44% Cr_2O_3, no ratio, delivered Atlantic ports was quoted at $25 to $27 per long ton until April and $24 to $27 for the balance of the year.

Strong competition from imported chromium alloys resulted in lower prices of chromium to consumers. For instance, the price of imported charge chromium started the year at 21 cents per pound of chromium, or 2 cents below the 23 cents per pound for domestic material. In April, the imported price dropped to a range of 20 to 21 cents per pound of chromium. To meet foreign competition, domestic producers lowered their price to 20 cents per pound in July, which caused a further reduction in the price of imported material to 19 to 19.5 cents per pound of chromium. In November, the domestic price for charge chromium ceased to be published. A similar price situation developed for domestic high-carbon ferrochromium which started the year at 26.7 cents per pound of contained chromium which was reduced to 23.7 cents in July. The price was withdrawn in October.

Selected chromium alloy prices published by Metals Week at midyear (July 13, 1972) were as follows:

Material	*Cents per pound of chromium*
High-carbon ferrochromium	23.7
Charge chromium	20.0
Imported charge chromium	19.0–19.5
Low-carbon ferrochromium (0.025% carbon)	39.5
Low-carbon ferrochromium (0.05% carbon)	38.0
Imported low-carbon ferrochromium (0.05% carbon)	35.0–36.0
Blocking chromium (high-silicon)	28.6
	Cents per pound product
Aluminothermic chromium metal	115
Electrolytic chromium metal	130

FOREIGN TRADE

Both exports and reexports of chromite dropped significantly compared with those of 1971; exports decreased 42% while reexports dropped 61%. Export shipments were to Mexico, 51%; Canada, 49%; and small quantities to three other countries. Reexports were shipped to five countries; Canada, 55%; Mexico, 33%; Spain, 7%; Ireland, 4%; and Morocco, 1%.

Ferrochromium exports increased 40% to 12,861 tons valued at $4,341,539. West Germany, 36%; Canada, 30%; United Kingdom, 23%; and Sweden, 9% were the leading recipients of shipments. Reexports of ferrochromium decreased to 78 tons from 625 tons in 1971. Canada received 86% of the reexports.

Chromium and chromium alloys (wrought and unwrought) and waste and scrap exports totaled 200 tons valued at $303,576. Of the 24 countries receiving shipments, Canada accounted for 23%, Jamaica 16%, Venezuela 10%, and the Netherlands 9%.

Exports of pigment-grade chromium chemicals totaled 166 tons, valued at $290,340. Canada received 54% of the shipments and the balance was dispersed among 18 countries. Exports of non-pigment-grade chromium chemicals totaled 1,265 tons valued at $1,526,092. Japan received 27%, Canada 19%, France 15%, Italy 9%, and 25 countries the balance.

Exports of sodium chromate and dichromate increased 31% compared with 1971 totals, rising to 4,035 tons. Canada was the leading recipient with 69% of the shipments, and 22 other countries accounted for the balance.

Imports of chromite in 1972 decreased 18% in quantity and 13% in value compared with 1971 totals. Imports from the U.S.S.R. rose 41% compared with those of 1971, while those from Turkey and the Republic of South Africa fell 70% and 41%, respectively.

Imports of ferrochromium accelerated, reaching a record high of 141,271 tons valued at $34,588,000. This compares with the former high year of 1971 when ferrochromium totaled 85,187 tons. The Republic of South Africa supplied 34% and Japan 21% of the low-carbon ferrochromium. High-carbon ferrochromium was supplied by the Republic of South Africa, 42%; Southern Rhodesia, 16%; and Finland, 9%.

[1] Revisions in 1969: Less than 3% carbon Western Africa n.e.c.—deleted. Republic of South Africa should read gross weight 22,050 short tons, chromium content 13,706 short tons ($5,503); 1970; delete Mozambique, Republic of South Africa should read gross weight 1,120 short tons, chromium content 620 short tons ($140).

Four countries, Norway, the Republic of South Africa, Southern Rhodesia, and Sweden, supplied 8,427 tons of ferrochromium-silicon valued at $846,106. Southern Rhodesia accounted for 72% of the total.

Chromium carbide imports from West Germany and the United Kingdom totaled 158 tons valued at $459,519. West Germany accounted for nearly 93% of the total.

Imports of chromium metal, unwrought and waste and scrap, increased to 1,894 tons from 1,632 tons in 1971. Total value rose to $3,791,079 from $2,965,641. Of the seven countries supplying imports, the United Kingdom accounted for 60% and Japan 27%.

Imports of chromium-containing pigments were as follows: Chrome green, 450 tons; chrome yellow, 7,530 tons; chromium oxide green, 1,383 tons; hydrated chromium oxide green, 183 tons; molybdenum orange, 659 tons; strontium chromate, 3 tons; and zinc yellow, 1,461 tons. Total value of these products was $6.3 million, 40% higher than in 1971. Chromium yellow accounted for 60% of total value of these products. The leading supplier was Japan, which furnished 49% of total value.

Sodium chromate and dichromate imports totaled 5,748 tons valued at $1,159,815; 10% less than in 1971. Imports were principally supplied by U.S.S.R., 44%; Japan, 33%; and the Republic of South Africa, 10%.

WORLD REVIEW

Brazil.—Cia. de Ferro Ligas da Bahia, S.A. (FERBASA) continued to be Brazil's principal producer of chromite and ferrochromium. Early in 1972, following a period of negotiations initiated in 1971, FERBASA reached an agreement with several Japanese groups (Mitsui & Co. and others) to form a new company, called Cia. de Mineração Serra da Jacobina (SERJANA), which will conduct exploration work for new chromite deposits. At the present time, the Japanese will not participate in FERBASA's ferrochromium operations. FERBASA plans to increase its low-carbon ferrochromium production with the installation of a 3,500-kilovolt-ampere electric furnace. Annual production capacity of the enlarged plant will be on the order of 5,512 short tons per year.

Brazilian Chrome Resources Development (BCRD) initiated an exploration program to develop additional reserves at the Pedrinhas chromium mine in the State of Bahia. Chromite is mined at Pedrinhas to supply FERBASA and for export. BCRD is owned by two Japanese trading companies and six Japanese consumers.

New Guinea.—American Metal Climax Inc. (AMAX) continued to explore a chromite deposit near the Sela River south of Lae.

[e] Estimate. [p] Preliminary.

[1] In addition to the countries listed, Argentina has produced less than 500 tons of chromite annually in each of the three years listed in the table, and Bulgaria, Cuba, North Korea and North Vietnam also produce chromite but available information is inadequate to make reliable estimates of output levels.

[2] Less than ½ unit.

[3] Exports.

India.—In 1969, the Geological Survey of India (GSI) initiated an extensive study of chromite occurrences in Andhra Pradesh, Bihar, Maharashtra, Mysore, Orissa, and Tamil Nadu, and has since assisted in the conservation of existing ore and in the improvement of the small-mine industry's operating methods. Currently, the GSI places the total chromite reserve at 13.9 million tons. Of the total, lump ore comprises 1.6 million tons; fines 4.7 million tons, and unclassified ore 7.6 million tons. A breakdown by type of ore indicates 3.9 million tons represents metallurgical and chemical-grade ores, and 10 million tons refractory-grade ore.

India's chromite production in 1971 decreased nearly 4% compared with that of 1970. However, the value of chromite production increased from $2.1 million in 1970 to $2.5 million in 1971. For the third consecutive year all chromite exports were to Japan. Shipments by grade of ore were as follows: Over 48% Cr_2O_3, 59,304 tons; 38 to 48% Cr_2O_3, 15,653 tons; and below 38% Cr_2O_3, 30,606 tons.

Ferrochromium production decreased from 14,708 in 1970 to 13,756 tons in 1971. The major producer, the privately owned Ferroalloy Corp. Ltd., accounted for 80% of India's output while the public sector firm, Industrial Corp. of Orissa, Ltd., produced 15%. The balance was produced by three other concerns, one of which was in the public sector. Ferrochromium exports fell sharply in 1971 to 4,625 tons from 9,274 in 1970. The United States received 52% of total exports.

A recently revised study by the Government of India Planning Commission estimates India's chromite demand pattern through 1983 as follows: 1973, 330,000 tons; 1978, 386,000 tons; and 1983, 408,000 tons.

Iran.—The Industrial Development and Renovation Organization of Iran was reported to be planning construction of a ferrochromium plant near Bandar Abbas with an annual capacity of 50,000 tons.

Malagasy Republic.—In 1972 Cie. Minière d'Andriamena (Comina) cutback production of chromite at its Malagasy mine owing to sales difficulty. In 1971, Comina stockpiled about six months output because of lack of sales. France and Japan are the principal recipients of Malagasy chromite.

Pakistan.—The West Pakistan Industrial Corp. (WPIDC) is a semi-government agency which plans and supports industrial projects in Pakistan. WPIDC earmarked $2.3 million for a ferrochromium processing plant in the North West Frontier Province, 74% of which would be financed by Chinese credit.

Philippines.—Output of chromite decreased 18% compared with that of 1971; 77% was classified as refractory-grade and 23% metallurgical-grade. Exports of refractory-grade chromite totaled 314,229 tons. The United States received 47%, Japan 15%, and the United Kingdom 12%; the balance was shipped to nine other countries. Japan received all of the 75,919 tons of metallurgical-grade chromite exported.

Rhodesia, Southern.—United Nations economic sanctions, which were applied in 1966, brought retaliation by the Rhodesian Government in the form of an embargo on mining news, primarily production data. Firm production data has been unavailable since 1965.

Rio Tinto (Rhodesia) Ltd. (RTR) reportedly requested government approval for building a chromium smelter complex at Eiffel Flats near Gatooma. Production could occur in 1975 depending on world demand and government approval. The company was also considering using the facilities as a custom smelter. In preparation, RTR acquired the total share capital of Rhodesian Mining Enterprises Ltd. and the claims and assets of Great Dyke Chrome Mines Ltd. Rhodesian Mining had two mines in operation, the Jester and Feoch mines, and the O'Meath mine on standby. Great Dyke Chrome mines held a large number of claims in the Darwendale area of the Great Dyke. RTR also had an option to purchase the entire share capital of Frances Mines Ltd.

South Africa, Republic of.—Chromite production in the Republic of South Africa totaled 1,635,000 tons and was down 10% compared with 1971 figures. Of the total, 504,000 tons was classified as less than 44% Cr_2O_3; 1,078,000 tons from 44 to 48% Cr_2O_3; and 53,000 tons as over 48% Cr_2O_3. Local sales of chromite accounted for 359,000 tons and exports 1,386,000 tons. Local sales and exports moved in opposite directions compared with 1972; local sales decreased 19% while exports increased 8%.

Despite the downturn of chromite production in South Africa, the Transvaal Consolidated Land and Exploration Co., Ltd., a subsidiary of Barlow Rand Ltd., reported annual chromite sales increased for its reporting period ending September 30. According to the firm's annual report, the group owns a substantial portion of South Africa's chromite reserves and the combined production of its three mines makes it the largest single producer of chromite in South Africa.

Initial work has been completed on increasing chromite production at the Grasvally Chrome mine owned by African Metal Corp. Ltd. (AMCOR) and operated by Cromore Ltd. Mining began in 1962 and for the past eight years production ran about 500 tons per month. The current expansion project when completed in early 1976 will bring production capacity to 275,000 tons annually, of which 220,000 will be available for export.

South Africa's ferrochromium output received a major boost when the Associated Manganese Mines of South Africa and United States Steel Corp.'s new plant at Machadodorp came into production in December. Full production capacity of the plant will be about 4,409 short tons per month.

AMCOR's new chromium ferroalloy furnace was near completion at yearend. The new furnace with a rated capacity of 50,000 tons of charge chromium annually will bring AMCOR's total ferroalloy production capacity to 125,000 tons annually, of which 80% will be available for export.

Sweden.—Airco Alloys AB, a wholly owned subsidiary of Airco Alloys and Carbide Div. of Airco Inc., brought onstream a 75,000-kilovolt-ampere furnace, reportedly the largest in the world for ferroalloy production. Although being used for ferrosilicon production, the firm also plans on using the facility for production of ferrochromium. The new unit replaces four smaller units at the plant and is equipped with a sand filter dust control system for removing pollutants.

Turkey.—Etibank was authorized to develop chromite deposits near Cakmak, Islahiye, Turkey. The agreement calls for extracting 500 tons of chromite per year. Etibank also signed similar agreements for development of chromite deposits at Kirkpinar and Kuzoluk.

International Mining Corp., Chrome Resources S.A., and Foote Mineral Co. joined forces to construct a plant for concentration of chromium ore in Turkey. Shipments of chromium concentrate were expected to begin late in the year.

Yugoslavia.—The geology of Yugoslavian chromite deposits was described.[5]

TECHNOLOGY

Processes for the production of stainless steel continue to be developed and improved. Most of the processes utilize lower cost high-carbon ferrochromium rather than higher cost low-carbon ferrochromium.

Joslyn Stainless Steel, a division of Joslyn Manufacturing and Supply Co. and a pioneer in the development of the argon-oxygen decarburization (AOD) process, believes that it has perfected a process for substituting nitrogen for a significant part of the argon used in the process. Spartan Steel and Alloy Ltd. (United Kingdom) also found that nitrogen can partially replace the more expensive argon.

Allegheny Ludlum, Inc., teamed up a basic oxygen furnace (BOF) with a hot blast cupola furnace at its Natrona, Pa., plant.[6] Stainless steel scrap, high-carbon ferrochromium, and molybdenum oxide are cold charged to the BOF furnace to which the cupola hot metal is added. Optimum charge rate has been 66.5% hot metal. Chromium recovery rates range from 88.7 to 92.5%.

For the production of most nickel stainless steel grades, Allegheny utilizes a vacuum refining process (AVR) which employs an electric furnace for melting and a vacuum refining unit. Decarburizing is achieved by injecting oxygen below the liquid metal surface while it is held at reduced pressure. Chromium yield in the AVR unit was reported at 98.1% and overall chromium recovery at 92.6%.[7]

Sweden's Uddeholm Steel Corp. developed a stainless steel process similar to the AOD process, but in place of argon to carry off the carbon monoxide, water vapor is injected through the furnace bottom. Reduced refractory wear is claimed; however, the process is limited to stainless grades containing less than 0.15% carbon. The firm reports a savings of $8 per ton in the manufacturing of stainless steel.

Outokumpu Oy (Finland) continued to develop a process for the production of electrolytic chromium. Chromium metal containing 200 to 300 ppm oxygen, 20 to 40 ppm nitrogen, and 10 ppm sulfur was purified in bulk to less than 1 ppm oxygen, 5 ppm nitrogen, and less than 5 ppm sulfur. The material was then processed into a wrought bar by direct extrusion in an evacuated sheath.[8] Small quantities of interstitial elements in chromium metal in the past has prevented processing commercial chromium metal to ductile metal.

An improved electrorefining process was developed for the preparation of high-purity chromium with low-interstitial content. High-purity commercial chromium metal was electrorefined in a chromic chloride ($CrCl_2$) electrolyte at cathode current densities of 40 to 210 amperes per square foot. Average current efficiency and chromium recovery were 96% and 99%, respectively.[9]

Two new chromium plating processes were developed that could substantially reduce repair and salvage costs. The first was an electrolytic process that can be taken to the automobile bumper. The second was a hard chromium plating system primarily intended for use in moldmaking and tool and die operations for salvaging worn or mismatched parts.

The Central Research Institute (India) reported the development of a self-regulating, high-speed chromium salt. The performance characteristics of the formulation demonstrate the following advantages over conventional plating: Higher production rate; formation of smoother, brighter, and harder deposits; less frequent need for accessories such as jigs; and elimination of control of critical constituents such as sulfate.[10]

Bureau of Mines researchers determined low-temperature heat capacities and high-temperature enthalpies calorimetrically for sodium chromate.[11]

Clays

By Sarkis G. Ampian[1]

Clays in one or more of the classification categories (kaolin, ball clay, fire clay, bentonite, fuller's earth, or common clay and shale) were produced in 47 States and Puerto Rico. Clay production was not reported in Alaska, the District of Columbia, Rhode Island, or Vermont. The States leading in output were Georgia, 6.2 million tons; Texas, 5.2 million tons; and Ohio, 4.1 million tons; followed in order by North Carolina, Alabama, and California. Georgia also led in total value of clay output with $132.3 million; Wyoming was second with $18.5 million. Compared with 1971 figures, clay production increased in 31 States and value increased in 29 States. Total quantity of clays sold or used by domestic producers in 1972 was approximately 5% higher than in 1971, and total value was approximately 10% higher. Both the total tonnage and value of clays produced were alltime highs. Modest increases in value per ton were reported for all clays except fuller's earth and kaolin, which declined slightly in value.

Kaolin in 1972 accounted for only 9% of the total clay production but for 45% of the domestic clay and shale value.

Table 1.—Salient clay and clay products statistics in the United States[1]

(Thousand short tons and thousand dollars)

[1] Excludes Puerto Rico.

DOMESTIC PRODUCTION, PRICES, AND FOREIGN TRADE, BY TYPE OF CLAY

KAOLIN

Domestic production of kaolin in 1972 and its reported total value increased 9%. The average unit value for all grades of kaolin in 1972 was $25.75 per ton, $0.04 lower than in 1971. Kaolin was produced in mines in 17 States. Two States, Georgia (74.6%) and South Carolina (12.8%), accounted for 87.4% of the total U.S. production in 1972. Arkansas ranked third, Alabama fourth, and Texas fifth. Output in 1972 declined in Arizona, Arkansas, Idaho, Ohio, Oregon, and Utah. Increased production was noted in California, Florida, Georgia, Missouri, Nevada, North Carolina, Pennsylvania, South Carolina, and Texas. A new producing State in 1972 was Minnesota.

Kaolin is defined as a white claylike material approximating the mineral kaolinite. It has a specific gravity of 2.6 and a fusion point of 1,785° C. The other kaolin-group minerals, such as halloysite and dickite, are encompassed.

During 1972 Burgess Pigment Co. added an additional flash calciner at its Sandersville, Ga., facility, and Engelhard Minerals &

Chemicals Corp. announced plans for expanding its calcined kaolin production capacity at McIntyre, Ga. Anglo-American Clay Corp. also announced expansion of its facilities at Sandersville. This expansion included new spray-drying equipment plus additional equipment to increase the production capacity of their high-brightness coating clays. Freeport Kaolin Co. and Georgia Kaolin Co. were installing large-capacity wet magnetic separators at their Georgia plants, while the J. M. Huber Corp. was expanding its existing magnetic separator facilities. Theile Kaolin Co. was also reportedly planning installation of magnetic separators at its Sandersville plant. High-intensity wet magnetic separators are used to remove iron-bearing contaminants from kaolin clays. Dresser Industries Inc. placed its new kaolin-calcining facility on stream at Kossee, Tex.

Kaolin was exported to 54 countries. The recipients were Japan, 24%; Canada, 22%; West Germany, 18%; Italy 12%; and the remaining countries, 24%. Generally, exports to all countries increased, except for those to Italy, France, West Germany, and Sweden which decreased 45%, 32%, 24%, and 10%, respectively. The kaolin producers reported the end use of their exports were paper coating, 48%; paper filling, 25%; rubber, 8%; and others, including firebrick, paint, and plastics, 19%.

Kaolin imports in 1972 continued the downward trend reported for a number of years, to 25,481 short tons valued at $736,000 from 44,622 tons valued at $907,000. The United Kingdom supplied over 96%; Canada, 3%; and 3 other countries supplied the remaining 1%.

BALL CLAY

Production and value reported for domestically mined ball clay in 1972 increased 12%. Tennessee mines provided 64% of the Nation's output, followed in order of output by Kentucky, Mississippi, Texas, California, Maryland, New York, and Indiana. Production in Kentucky, California, Maryland, Mississippi, and Tennessee increased over that reported in 1971.

Ball clay is defined as a plastic, white-firing clay used principally for bonding in ceramic ware. The clays are of sedimentary origin and consist mainly of the clay mineral kaolinite and sericite micas.

In 1972 American-Olean Tile Co. announced plans for a future factory for manufacturing quarry tile at Roseville, Calif. NL Industries, Inc., acquired Bell Clay Co. of Gleason, Tenn. Bell's complete line of ball clays were to be marketed through NL Industries' TAM Division, and will supplement the clays and other materials that the division supplies.

The average unit value for ball clay reported by domestic producers rose in 1972 to $15.99 per ton, an increase of $0.04 per ton. Chemical Marketing Reporter, December 25, 1972, listed ball clay prices as follows:

Domestic, air-floated, bags, carload lots, Tennessee, per ton	$18.00–$22.00
Domestic, crushed, moisture-repellent, bulk, carload lots, Tennessee, per ton	8.00–11.25
Imported, air-floated, bags, carload lots, Atlantic ports, per ton	70.00
Imported, lump, bulk, Great Lakes, per ton	40.50

Ball clay exports in 1972 amounted to 87,000 short tons valued at $1.7 million, compared with 77,000 tons worth $1.5 million in 1971. Exports increased 13% over that shipped in 1971, while the value was 12% higher. The unit value of ball clay exported in 1972 declined $0.11 per ton, from $19.55 in 1971 to $19.44. These shipments were made to 21 countries. The major recipients were Canada, 48%, and Mexico, 44%; 19 countries accounted for the remaining 8%.

[1] Includes California, Indiana (1972), Kentucky, Maryland, Mississippi, New Jersey (1971), New York, and Texas.

FIRE CLAY

Fire clay sold or used by domestic producers in 1972 was reported at 3,580,635 short tons valued at $29.2 million. Fire clay is defined as detrital material, either plastic or rocklike, containing low percentages of iron oxide, lime, magnesia, and alkalies to enable the material to withstand temperatures of 1,500° C or higher. Fire clay is basically kaolinite but usually contains other materials such as diaspore, ball clay, bauxite clay, and shale. Fire clays commonly occur as underclay below coal seams and are generally used for refractories. Some fire clay was previously reported in other end uses.

Fire clay production was reported in 1972 from mines in 21 States. The first four States in rank, Missouri, Ohio, Pennsylvania, and Alabama, accounted for 79% of the total domestic output.

In 1972 Louisville Fire Brick Works increased capacity for special hand-molded firebrick shapes at its Grahn, Ky., plant.

Exports of fire clay decreased from 162,000 short tons worth $3.6 million in 1971 to 124,000 tons valued at $2.9 million

Table 11.—Fire clay sold or used by producers in the United States, by State [1]

in 1972. Fire clay exports declined 23% in tonnage and 19% in value. The price of exported fire clay increased by $1.42 to $23.43 per ton.

Fire clay was exported to 41 countries, with Canada and Mexico receiving 40% and 38%, respectively. The other 39 countries received the remaining 22%. No imports of fire clay were reported during 1972.

There are no price quotations in domestic journals for fire clay, but the per-ton value reported by producers ranged from $2 to about $9. The reported average unit value for fire clay produced in the United States increased 31% from $6.24 per ton in 1971 to $8.15 in 1972.

BENTONITE

Bentonite production in 1972 increased 4% in tonnage and 5% in value over 1971. A general increase in domestic consumption, particularly in drilling mud, animal feed, and oil filtering uses, offset decreased exports and a decline in foundry sand applications.

Bentonite was produced in 15 States. Increased bentonite production was reported for all States except Arizona, Colorado, Idaho, Mississippi, Oklahoma, South Dakota, and Utah.

Generally, the high-swelling or sodium bentonites are produced chiefly in Wyoming, Montana, and South Dakota. The calcium or low-swelling bentonites are produced in the other States.

Dust collection and control equipment was installed by Federal Bentonite Co. and Kaycee Bentonite Co. in their Wyoming plants.

Chemical Marketing Reporter, December 25, 1972, quoted bentonite prices as follows: Domestic, 200 mesh, bags, carload lots, f.o.b. mines, $14.00–$14.40 per ton; and imported Italian, white, high-gel, bags, 5-ton lots, ex-warehouse, $116.60 per ton. The average unit value reported by producers of domestic bentonite sold or used in 1972 was $10.60, a slight increase from the $10.46 average of the previous year. Per-ton values reported in the various producing States ranged from $3 to $23, but as in 1971, the average value reported by the larger producers was near the Wyoming average figure of $10.14.

Bentonite imports in 1972, including chemically activated and special-purpose Italian material, totaled 2,853 short tons valued at $229,000 compared with 2,393 tons valued at $194,000 in 1971. The 2,853 tons of chemically activated bentonite was imported from six countries, with Canada supplying 49%; Mexico, 29%; West Germany, 11%; Japan, 10%; and Ireland and the United Kingdom the remaining 1%. Imports of Italian bentonite in 1972 increased from 66 short tons in 1971 to 127 tons.

Bentonite exports in 1972 decreased from 663,000 short tons in 1971 valued at $16.2 million to 521,000 tons valued at $15.1 million. Although the tonnage exported decreased 21% from that shipped in 1971, the value decreased only 7%. The lesser decline in value was the result of the unit value of exported bentonite increasing $4.58 per ton, from $24.43 per ton in 1971 to $29.01 per ton. This increase in per ton value was attributed to a large decline in

Table 12.—Bentonite sold or used by producers in the United States, by State

the amount of lower cost bentonite shipped for iron ore pelletizing. Exports in previous years consisted of a larger percentage of the lower cost pelletizing grades. Domestic bentonite producers were facing increased competition in foreign markets. Bentonite from the Greek island of Milos was reportedly being blended with the U.S. clay for pelletizing Canadian taconite ores on a large scale.

Bentonite was exported to 71 countries, a decrease of 4 from the previous year. The major recipients were Canada, 56%; Australia, 9%; West Germany, 7%; United Kingdom and Singapore, 6%; each; and others, 16%. Domestic bentonite producers reported the end use of their exports were iron ore pelletizing, 43%; foundry sand, 40%; drilling mud, 13%; and others, including animal feed, oil refining catalysts, and waterproofing and sealing, 4%.

Table 13.—U.S. exports of bentonite as reported by producers in 1972, by use

Use	Short tons
Drilling mud	56,666
Foundry sand	167,130
Pelletizing (iron ore)	183,458
Other [1]	15,840
Total	423,094

[1] Includes animal feed, oil refining catalysts, waterproofing and sealing, and other uses.

FULLER'S EARTH

Production of fuller's earth in 1972 declined 3% in quantity and the total value declined 5%. The unit value assigned by domestic producers decreased $0.61 in 1972 to $23.08 per ton. This decrease in value was due primarily to the lower values reported by Florida producers. Georgia producers reported modest increases in unit value.

Fuller's earth production was reported from operations in eight States. The top two producing States, Georgia (41%) and Florida (36%), accounted for 77% of the domestic production. The other six States accounted for the remaining 23%. Georgia, Mississippi, and Tennessee showed gains in production, while Illinois, California, Florida, Texas, and Utah declined.

Fuller's earth is defined as a nonplastic clay or claylike material, usually high in magnesia, which has adequate decolorizing and purifying properties.

Production from the region that includes Attapulgus (Decatur County), Ga., and Quincy (Gadsden County), Fla., is composed predominantly of the distinct lath-shaped amphibole clay mineral attapulgite. Most of the fuller's earth produced in the other areas of the United States contains varieties of montmorillonite.

Prices for fuller's earth were not publicly quoted in 1972, but the per-ton values reported by producers ranged from $14 to about $29.

Table 14.—Fuller's earth sold or used by producers in the United States, by State

State	1971		1972

Total	1,013,914	24,019,616	988,538	22,818,119

[1] Includes California, Illinois, Mississippi, Tennessee, and Texas.

Exports of fuller's earth to 40 countries increased from 27,000 short tons in 1971 to 39,000 tons valued at $1.7 million in 1972. Export tonnage increased 44% and its valued increased nearly 47%. The unit value of exported fuller's earth rose nearly $0.68 per ton. The major recipients were the United Kingdom, 26%; Canada, 21%; and other countries, the remaining 53%.

Imports of fuller's earth in 1972 were 43 short tons valued at $3,000, all from the United Kingdom. Imports increased nearly 23%.

COMMON CLAY

The domestic production of common clay and shale in 1972 totaled 46.1 million short tons valued at $74.0 million. Com-

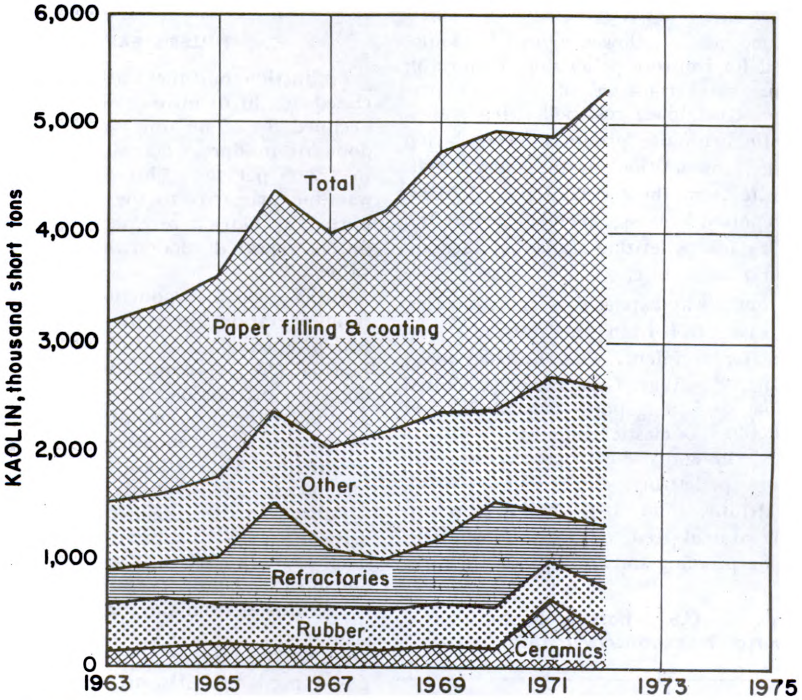

Figure 1.—Kaolin sold or used by domestic producers for specified uses.

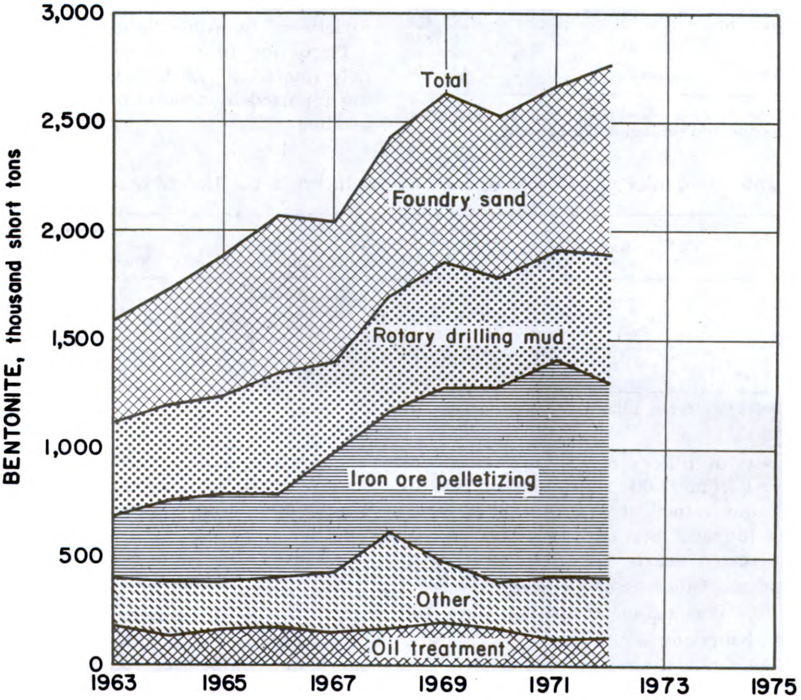

Figure 2.—Bentonite sold or used by domestic producers for specified uses.

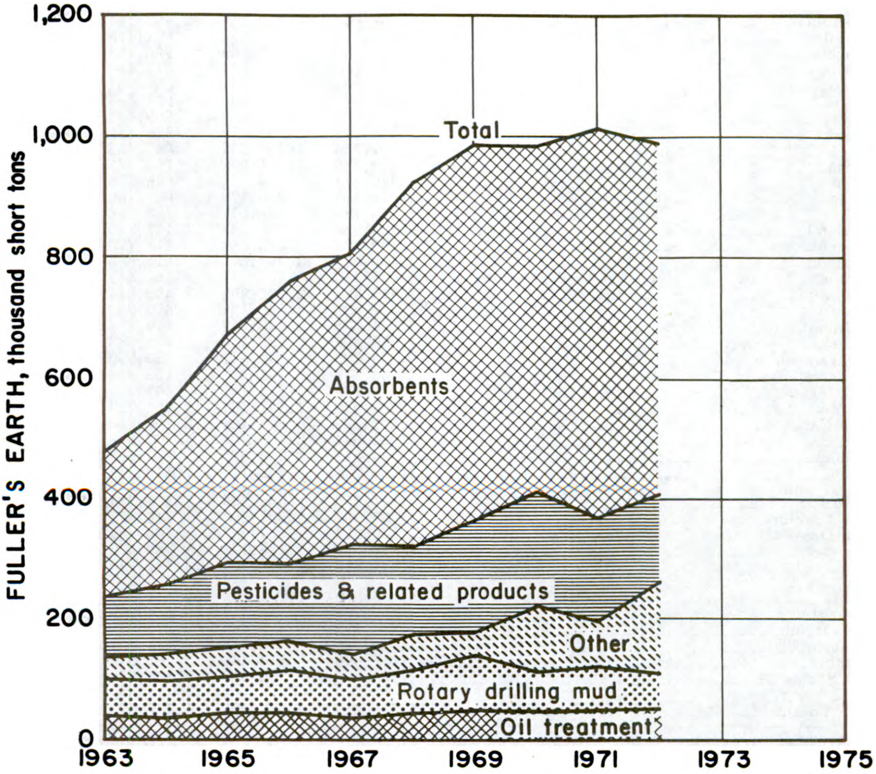

Figure 3.—Fuller's earth sold or used by domestic producers for specified uses.

mon clay and shale represented 78% of the quantity and 25% of the value of the total clay and shale produced domestically in 1972. In addition, Puerto Rican production of common clay and shale was reported at 360,724 tons valued at $382,296. Domestic output in 1972 increased 4% over that reported for 1971.

Common clays and shales are for the most part used by the producer in fabricating or manufacturing a product. Less than 10% of the total clay and shale output was sold. The average unit value for all common clay and shale produced in the United States in 1972 was $1.60 per short ton, $0.08 more than in 1971. The range in unit value reported for the bulk of the output was from $1 to $2 per ton.

Common clay is defined as a clay or claylike material which is sufficiently plastic to permit ready molding and vitrification below 1,100° C. Shale is a consolidated sedimentary rock composed chiefly of clay minerals which has been both laminated and indurated during burying under other sediments. These materials are used in the manufacture of structural clay products, such as brick and drain tile, portland cement clinker, and bloated lightweight aggregate.

During 1972 General Shale Products Corp. and Pine Hall Brick and Pipe Co. announced plans to increase brick production capacities. General Shale's expansions

[2] Includes Hawaii, Idaho, Nevada, North Dakota, and data indicated by symbol W.

were scheduled at its fully automated Knoxville, Tenn., plant and at Marion, Va. The expansion at Marion included a new 40-million-brick-per-year kiln. Pine Hall had broken ground for an addition to its No. 4 plant in Madison, N.C., which was completed and put into operation in 1970. The enlarged facility would double Pine Hall's capacity by increasing production by 40 million bricks. Alliance Brick Corp. was purchased by the Whitacre-Grier Fireproofing Co. of Waynesburg, Ohio. Whitacre presently devotes its production equally to refractories for the steel industry and architectural clay products. Alliance's modern brick plant with its two tunnel kilns was viewed as supplementing Whitacre's operations. An enlargement of its Tulsa, Okla., plant from a present capacity of 16 million bricks per year to 40 million per year was outlined by the Acme Brick Co. The Oklahoma Brick Corp., of Oklahoma City, Okla., also announced plans to fully automate its clay brick plant. The kilns in the newly automated facility will highlight a highly efficient moisture removal system.

Georgia Lightweight Aggregate Co. has contracted with Fuller Co., Catasauqua, Pa., for a new rotary kiln processing system to be installed at its Rockmart, Ga., plant late in 1972. Dust collecting and control systems were scheduled for the Erwindale, La., plant of Big River Industries, Inc., and at Vulcan Material Co.'s expanded shale plant near Bessemer, Ala. The Onondaga Lightweight Aggregate Corp.'s newly acquired fly ash sintering plant in Queens, N.Y., formerly owned by Consolidated Edison, was successfully moved, renovated, and put on stream producing the corporation's aggregate, Onolite. Plainville Corp. unveiled its redesigned "Masslite" expanded shale facility at Plainville, Mass. The redesigned Masslite plant features a more efficient operation and environmental controls.

Exports of common clay and shale are not tallied by the U.S. Department of Commerce. Most countries have local deposits of either clays or shales which are adequate for manufacturing structural clay products, cement clinker, and lightweight aggregates, and thus have no need to import such material.

CONSUMPTION AND USES

The manufacturing of heavy clay products (building brick, sewer pipe, drain tile), portland cement and clinker, and lightweight aggregate accounted for 38%, 21%, and 18%, respectively, of the total 1972 domestic consumption of clays. In summary, 77% of all clay produced in 1972 was consumed in the manufacture of these clay- and shale-based construction materials. The above clay tonnage relationships were similar to those reported for 1971. The utilization of clays in 1972 for heavy clay products and portland cement increased 2% and 8%, respectively, over that reported in 1971. This increased clay consumption in building products reflected the general increase in construction activity.

Heavy Clay Products.—The values reported for shipments of heavy clay products in 1972 rose by 13% to $722 million from the 1971 value of $642 million. The trends in corresponding quantities were less consistent. Thousand-unit counts for unglazed facing tile, floor and wall tile, building bricks, and the tonnage of vitrified sewer pipe increased 33%, 12%, and 11% respectively, over that shipped in 1971. Shipments in 1972 of unglazed structural tile, glazed facing tile and the tonnage of vitrified sewer pipe showed decreases of 34%, 15%, and less than ½% respectively, compared with shipments in 1971.

Lightweight Aggregate.—Consumption of clay and shale in the making of lightweight aggregate increased in 1972 to an alltime high of 10,750,217 short tons. This was a 5% increase over the 10.2 million short tons used in 1971.

The tonnage of raw material mentioned in tables 16 and 19 for lightweight aggregate production refers only to clay and shale and does not include the quantity of slate and blast furnace slag similarly used. In 1972, a total 1,269,646 short tons of slate was expanded for lightweight aggregate, an increase of 54% over the 1971 figure of 824,787 tons. In addition, the National Slag Association reported the amount of slag used as lightweight concrete aggregate and in block manufacture decreased 8% in 1972 from 1,377,000 short tons in 1971 to 1,264,000 tons.

Refractories.—All types of clay were used in manufacturing refractories. Fire clay and kaolin accounted for 85% and 12%, respectively, of the total clays used for this purpose. Minor tonnages of ball clay (2%) and bentonite, fuller's earth, and common clay and shale (the remaining 1%), were also used, primarily as bonding agents.

The tonnage used for refractories in 1972 increased from 6% in 1971 to 7% of the total clays produced. This slight increase in the use of clay-based refractories reverses a downward pattern set for a number of years. The increase was due primarily to an upsurge in the production of refractory aggregates which offset the continuing decline in the production of more conventional brick-type refractories. Refractory aggregates are used mostly in plastic, ramming, and castable mixes.

Filler.—All clays are used to some extent as fillers in one or more areas of use. Kaolin and fuller's earth are the principal filler clays. Kaolin was used in the manufacture of a large number of products, such as paper, rubber, plastics, paint, and fertilizers. The other important filler clay, fuller's earth, was used primarily in pesticides and fertilizers. Clays in pesticides and fertilizers are used either as carriers, diluents, or prilling agents.

A total of 5% of the clay produced in 1972 was used in filler applications. Kaolin accounted for 92% and fuller's earth for 6% of all the clay used for these purposes. The other clays accounted for the remaining 2%. The consumption of kaolin, except for plastics which decreased 10%, increased in the amount used, ranging from less than 1% to 90%. Kaolin used in paper filling and coating increased less than 1%, in paint 16%, in fertilizer 30%, in rubber 40%, and in pesticides 90%. Total quantity of fuller's earth used in insecticides and fungicides decreased 20%.

Absorbent Uses.—Absorbent uses for clays, approximately 586,296 short tons, consumed slightly less than 1% of the total 1972 clay production. Demand for absorbents in 1972 decreased 8% from that reported for 1971. Fuller's earth was the principal clay used in absorbent applications; bentonite was used to a lesser degree. Fifty-nine percent of the entire fuller's earth output was consumed for these purposes. Demand for clays in animal litter, representing 41% of the 1972 absorbent demand, decreased 14% from that reported for 1971. Demand for use in floor absorbents, chiefly to absorb hazardous oily substances, represented the remaining 59% of absorbent demand and decreased 3% from the 1971 figure.

Drilling Mud.—Demand for clays in rotary-drilling fluids increased 4% in 1972 from 583,712 short tons used in 1971 to approximately 596,180 tons. Drillings muds consumed slightly less than 1% of the entire 1972 clay production. Swelling-type bentonite is the principal clay used in drilling mud mixes, although fuller's earth or nonswelling bentonite is also used to a limited extent. Bentonite and fuller's earth accounted for nearly 100% of total amount of clay used for this purpose. Small amounts of kaolin, ball clay, and common clay and shale were used in specialized formulations.

Floor and Wall Tile.—Common clay and shale, ball clay, kaolin, and fire clay, in order of demand, were used in manufacturing floor, wall, and quarry tile. This tile end-use category accounted for less than 1% of the total clay production in 1972. Demand in 1972, 452,014 short tons, decreased over 7% from that shown in 1971.

Pelletizing Iron Ore.—Bentonite is used as a binder in forming iron ore pellets prior to the blast furnace operation. Demand, reversing a general trend for several years, decreased 9% in 1972, to 707,187 short tons. This decline in the use of bentonite for iron ore pelletizing reflects the inroads made by the lower cost Greek bentonites into a traditional U.S. clay market. Of the total bentonite produced in 1972, about 26% of the swelling variety (a decrease from the 37% in 1971) was consumed for this purpose. U.S. deposits continued to be the major source for swelling bentonites.

Pottery.—The total demand for clays in the manufacture of pottery, sanitary ware, and related products, excluding clay flower pots, accounted for 1% of the total 1972 clay output. The total clay demand, principally ball and kaolin clays, rose about 4% from 591,167 short tons in 1971 to 616,494 short tons in 1972.

Table 16.—Clays sold or used as reported by producers in the United States in 1972, by kind, and use, including Puerto Rico

NA Not available. XX Not applicable.

[1] Excludes data for mullite and extra-high-alumina refractories. These products are included with mullite and extra-high-alumina brick and shapes in the nonclay refractories section.

[2] Now included with fire clay (including semisilica) brick and shapes, except superduty.

[3] Includes data for bonding mortars which contain up to 60% Al_2O_3, dry basis. Bonding mortars which contain more than 60% Al_2O_3, dry basis, are included in the nonclay refractories section.

[4] Represents only shipments by establishments classified in "manufacturing" industries, and excludes shipments to refractories producers for the manufacture of brick and other refractories.

[5] Includes data for calcined clay, ground brick, and siliceous and other gunning mixes.

WORLD REVIEW

Australia.—The Australian Mineral Development Laboratories at Frewville, South Australia, was requesting quarrying and mining companies in the Sydney and Melbourne areas to submit samples of clay, shale, or potentially bloating material for a preliminary evaluation of bloating behavior up to 1,350° C. These evaluations were part of the Laboratories' investigations throughout Australia for new sources of lightweight aggregate material capable of being used in heavy construction. The Laboratories were also planning tests to develop brick and tile blends using lightweight sands and fines.[2]

Abaleen Minerals NL reported plans to begin kaolin production early in 1973, from its undisclosed southern deposit. Preliminary geological studies of the deposit proved some 20 million tons of exploitable ore, but indications were that this figure could be much higher. Although the kaolin has a high titanium content, which tends to stain paper, Abaleen planned to sell to the papermakers.[3]

---

[2] Industrial Minerals. No. 62, November 1972, p. 29.

Ataka and Co. Ltd., Japan, announced plans to expand its kaolin mining and processing project at Greenbushes, Western Australia, 135 miles south of Perth. Expansion of the Greenbushes pilot plant will increase production to 3,000 tons per month, at a cost of $1.5 million.[4]

Mineral Deposits Ltd. reported conducting feasibility studies on bentonitic clays from several localities with Baroid Australia Pty. Ltd., an associated company.[5] The Steetley Company, Ltd., acquired Commercial Minerals Pty. Ltd. of Newcastle, New South Wales. Commercial Minerals, among its activities, extracted and produced calcined flint clay, used widely as a refractory. This latest acquisition by Steetley, a vertically integrated United Kingdom refractory producer, continued the groups' diversification and complements its basic refractory products.[6]

English China Clay, Ltd., put a new kaolin processing plant on stream in Victoria. The new plant's annual capacity of 36,000 short tons per year of wet processed products was slated for expansion within the next few years to 90,000 short tons per year.[7]

Canada.—A decision in midyear 1973 was expected on a joint venture between Algoma Central and an unnamed firm to exploit Algoma's 200-million-ton silica-kaolin deposits 50 miles north of Hearst, Ontario. Algoma and its partner, experienced in kaolin mining, processing, and marketing, were planning milling at a rate of 600,000 tons per year to yield 80% silica, 15% kaolin, and 5% waste. The kaolin would be upgraded to about 83% brightness by a process developed jointly with the Ontario Research Foundation for use in papermaking.[8]

Egypt, Arab Republic of.—A joint scientific program was announced between Egypt and Czechoslovakia to develop the

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Brazil, People's Republic of China, East Germany, Lebanon, Southern Rhodesia, and Yugoslavia also produced kaolin, but information is inadequate to make reliable estimates of output levels. Morocco produced less than 500 tons in each of the years covered by this table.

[2] Kaolin sold or used by producers.

[3] Includes kaolinite clay.

[4] Figure apparently represents marketed output, including some crude kaolin and some washed kaolin.

[5] Less than ½ unit.

[6] Year beginning March 21 of that stated.

[7] Data given are for ceramic and pottery and paper filler clays.

[8] Includes ball clay.

Total	1,189,876	1,220,240	1,206,702

[e] Estimate. [p] Preliminary.

[1] In addition to the countries listed, France, Iran, Japan, Turkey, and the United Kingdom have reportedly produced fuller's earth in the past and may continue to do so, but output is not reported and available information is inadequate to make a reliable estimate of output levels. Similarly, no information is available on output in the Communist nations of Europe and Asia, but at least some of them also are presumably producing fuller's earth.

[2] Data are for year ending June 30 of that stated.

newly discovered bentonite deposits in Fayyum for use in oil well drilling.

France.—Installation of additional equipment at Engelhard Minerals & Chemical Corp. and Solvay's jointly owned kaolin facility in Brittany was nearing completion. The additional equipment was designed to upgrade the plant production to paper-coating quality. Plant capacity was estimated at 110,000 short tons per year.[9]

Germany, West.—Sued-Chemie A.G. and Girdler-Suedchemie G.m.b.H. of Munich announced that their recently appointed agents for bleaching earths and catalysts, Production Chemicals (Rochdale) Ltd., United Kingdom, will provide detailed technical services.[10]

Guyana.—Final arrangements were made with a participating Japanese company, Nisho-Iwa Co., for erecting a kaolin processing plant. The entire planned production was scheduled for export to Japan.

---

[9] Work cited in footnote 7.

[10] Industrial Minerals. No. 55, April 1972, p. 42.

India.—The Government, in response to disappointing performances by selected industries, proposed establishing a holding company to control future development of the steel, coking, coal, and refractories industries.

Indonesia.—China clay mined at Togaret, Minahasa Regency, in Sulawesi, by P. T. Usis in partnership with Kanematsu Cosho, Ltd., was exported entirely to Japan. China clay recovered from the other kaolin deposits, Bangka and Belitung Islands, was used by the principal domestic consumer, P. T. Keramika Indonesia Asosiasi.

Italy.—A permit to exploit Sardinian bentonite deposits was granted to C. Laviosa S.p.A. of Leghorn. Laviosa was also planning to build a plant at San Antioco on a 7 acre site. Annual production of bentonite was expected to amount to 200,000 tons. Sud Chemie Italia S.p.A. released plans for producing activated bentonite locally from Sardinian clays in a plant to be built by Breda Progetti e Costruzioni.[11]

Ivory Coast.—The Government was considering plans for erecting a plant 30 miles from Abidjan near a large clay deposit at Plinhim on the Comeo River, capable of producing 260,000 cubic yards of lightweight aggregate per year. The Ceram-Anten Co. announced plans for constructing a second facility in Abidjan for manufacturing mosaic and enameled ceramics. The second facility would enable Ceram-Anten to treble tile production to 3,500,000 square feet. A new factory for producing sanitary fixtures, dishes, and faience tiles was also scheduled. The new factory was to be located adjacent to a large deposit said to contain an estimated 4,500,000 cubic yards of white fire clay, 10 miles northeast of Abidjan.[12]

Malaysia.—The Japanese Sanyo Paper and Pulp Co. kaolin operations were started up during the year. The new operation reportedly increased Malaysian kaolin production significantly.[13]

Pakistan.—West Pakistan Industrial Development Corp. was setting up its china clay processing plant at Shahderi in Swat. The plant scheduled for completion in early 1973 was reported to be capable of producing nearly 5,000 tons of water-washed clay annually.[14] Pakpor Ceramics of Lala Musa has acquired licenses to import undisclosed quantitites of ceramic-grade china clay.[15]

South Africa, Republic of.—A deposit of "potentially high-grade" china clay has been discovered on a farm in the Cato Ridge area, between Durban and Pietermaritzburg. The Johannesburg Consolidated Investment Corp. has been contracted with for mining the clay.[16]

Sri Lanka.—A geological survey conducted by the Sri Lanka Ceramic Corp. succeeded in locating nearly 350,000 tons of kaolin in 10 acres of land near Bolgoda. The corporation was negotiating with Japanese firms who were interested in setting up a local ceramic factory, exclusively for export production.

A market survey conducted earlier by the corporation disclosed a large potential market, particularly in the Middle East, for the corporation's "batik" designed ceramics.[17]

Surinam.—The kaolin underlying the large bauxite deposits of the eastern coastal plain near Onverdacht and Moengo was reported to be suitable for papermaking. Higher quality kaolin deposits were unfortunately associated with a few weathered pegmatites.[18]

Thailand.—Kaolin production continued to increase dramatically. Production in 1972, nearly 12,000 short tons, represented a fourfold increase over that produced in 1970. Exports to Japan accounted for most of the increased production.[19]

Turkey.—A newly formed company, Kaolin Ticaret ve Sanayii, A.S., was planning to set up facilities to exploit a kaolin deposit in Eskişehir. Most of the kaolin production was intended for ceramic manufacture in domestic and overseas markets.[20]

[19] U.S. Bureau of Mines. Mineral Trade Notes, V. 69, No. 7, July 1972, p. 18.

[20] Industrial Minerals. No. 54, March 1972, p. 36.

Samas Sanayii Madenleri, A.S., a Turkish company, was awaiting financial backing to exploit a bentonite deposit near Reşadiye, Tokat, in northeastern Turkey. A proposed plant, pending negotiations with knowledgeable U.S. companies for supplying the needed processing equipment and expertise, was scheduled to produce between 30,000 and 40,000 tons of Wyoming-type swelling sodium bentonite annually. The proposed Reşadiye plant would include the usual drying, grinding, and packing facilities. Most of the plant's output was intended for export to European and Middle Eastern oil producing regions. The deposit, delineated nearly 5 years ago, was estimated to contain over 15 million tons of clay reserves in the present areas alone.[21]

United Kingdom.—Hepworth Ceramic Holdings, Ltd., acquired both Joe Kitson and Sons (Minerals) Ltd., and Thomas Temperley and Son, Ltd. Kitson has extensive clay-bearing land at Denby Dale in Yorkshire, which is near their main pipe-making works. Temperley manufactures and markets sanitary pipes and fittings and is based at Bacup, Lancashire.[22]

The Cawoods Refractories, Ltd., plant at Belvedere in Kent was being enlarged to meet the increasing demand for the firm's high-purity refractory aggregates. The new facility was scheduled to be on stream by the end of 1973.[23]

Watts, Blake, Bearne and Co., Ltd., (WBB) continued expansion of its ball clay production and raw materials handling capabilities. Development of their Courtmoor pit, North Devon, was well advanced, and increased production was planned for 1973. The firm's Cornwood New Plant for china clays was completed and capacity was increased by at least 50%. The new plant facilities include an automatic pressroom, band dryers, thickeners and automatically fed wet and dry storage areas. The dry storage bunkers have a 12,000-ton capacity.[24]

Agreement has been reached between Steetley Co. and NL Industries, Inc. (U.S.) on their joint bentonite derivatives operations. This joint venture by Steetley complements its newly acquired interest in the German bentonite firm, Bentone Chemie G.m.b.H., near Bremerhaven.[25]

The application of English Clays Lovering Pochin and Co., Ltd. (ECLP) to extend its 140-year-old clayworks on the southern edge of Dartmoor National Park continued in abeyance. This particular expansion has aroused considerable local opposition. ECLP's planning for many decades hung upon this Dartmoor extension.[26]

U.S.S.R.—Reports of a wet kaolin processing facility, using Japanese technology, of unknown capacity, location, and quality, continued to circulate throughout the industry.

TECHNOLOGY

Concomitant production of metallurgical-grade alumina and portland cement clinker from kaolin-type clays by a lime sintering technique was described in a patent.[27] Initially kaolin is admixed with sufficient limestone to form base soluble calcium monoaluminate and insoluble calcium disilicate during lime sintering. Aluminum trihydrate is precipatated from the digested sinter solution by carbonating. The precipitate is subsequently calcined to the desired alumina. The insoluble calcium disilicate solid residue, from the digestion step, is mixed with sufficient limestone and fired to form a low aluminate containing portland cement clinker. Another patent covering a method applicable to producing alumina from clays by a combined reducing then calcining approach was issued.[28] The method involves reducing an alumino silicate ore and a potassium sulfate-bearing ore, such as polyhalite and langbeinite, and then calcining the reductants to form base soluble potassium aluminate and insoluble silicates. The reducing step reaction successfully decomposes the reactants and produces H_2S. The aluminate is separated from the insoluble silicates KOH and/or K_2CO_3 solution and precipitated as $Al(OH)_3$ with either SO_2 or CO_2. The aluminum trihydrate is calcined to yield alumina. Some of the potassium carbonate or sulfite is recylced back into the processing stream, and the balance is converted to marketable potassium salts such as potassium sulfate or potash.

The efficient conversion of aluminum nitrate solution to cell-grade alumina was outlined in another patent.[29] This difficult conversion of aluminum nitrate solution was a longstanding problem associated with the nitric acid processes for "opening-up" clays. The conversion was accomplished by introducing the solution into a fluidized bed under conditions that allow recovery of the bulk of the nitrate values as nitric acid vapor while forming a residual hydrous aluminum nitrate solid. The solid is heated further to remove residual water and nitrate values and to convert the alumina to α- alumina.

A process for the direct production of aluminum-silicon alloys, containing more than 50% by weight of aluminum, from alumina-bearing ores was patented.[30] The alloys are produced by reducing stoichiometric amounts of aluminum and silicon along with predetermined amounts of water of hydration. Thermal reduction is successfully carried out with a materials throughput rate adequate to effect hydration but insufficient for densification and induration. Densification and induration of the material, prior to introduction to the furnace reaction zone, could be detrimental to the alloying reactions. A patent for producing aluminosilicate alloys by directly industry participation in building and opalso granted.[31] Sized ores, such as kaolin clays, bauxite, and kyanite, are fluidized in a stream of chlorine gas between 950° and 1,200°C sufficiently to volatilize the iron and titanium contaminants, thereby leaving the residual aluminum-silicon alloy.

Alumina from nonbauxite ores was the topic of a comprehensive report issued by a panel of the National Academy of Sciences.[32] The most promising domestic sources of alumina (other than commercial bauxite) were reviewed, basic approaches to the processing of clays and other sources were examined, and the most workable processes were appraised. Hydrochloric and nitric acid processes for treating clays appeared to be the most promising for economic production of alumina from nonbauxitic ores. Experimental and pilot plant data on other processes and/or ores were judged to be noncompetitive with the acid processes. The panel also recommended joint Government and aluminum chloridizing aluminosilicate materials was erating two 5-ton-per-day alumina plants. One plant was to use the "promising" hydrochloric acid technique, and the other the "best" proposed nitric acid method. The Georgia Department of Trade and Industry (GDTI), responding to the panel's recommendation, proposed a joint venture with the Federal Government using local supplies of kaolin as feedstock.[33]

The Georgia Institute of Technology, in a separate report prepared for the GDTI, recommended using the Hyde-Margonlin nitric process for the joint venture.[34] The alumina can be produced by this process from kaolin for $54 per ton commercially or only $4 above prices for bauxite alumina.

A detailed article on the kaolin industry in the United Kingdom was published.[35] The article covered mining and processing techniques, technological advances, environmental issues, markets, products, individual companies, and the future of the kaolin industry in Great Britain. The smaller scale European and Japanese kaolin industries were surveyed thoroughly in another report.[36] Selected mining and processing methods used by the California clay industry, in Amador, Calaveras, Kern, and Mono Counties, along with a discussion on the recovery of alum and alumina from other California ores, were highlighted in a State publication.[37]

The geologic relations, exploration and development trends, and consumption patterns for kaolins of the Southeastern United States were presented at the annual AIME meeting.[38] A similar oral presentation on the ball clays of Tennessee and Kentucky was also given at the annual AIME meeting.[39] A comprehensive thesis on the occurrences, properties, and uses of fuller's earth, bentonite, attapulgite, other absorptive clays, and the kaolin industry of the South was published.[40] An article discussing ore controls in the Eufaula bauxite-kaolin district in southeastern Alabama, an important source of domestic fire clays, its expanding mining operations, and the difficulties in finding ore reserves was published.[41] The investigation of the Eufaula district ores included detailed geological mapping of mines, in part based on auger and core drilling in selected areas combined with mineralogical analyses.

The reaction products in clay-lime-water systems, including those containing kaolin, under conditions appropriate to soil stabilization, have been extensively studied and reviewed.[42] The reaction products fall into two main categories, hydrous calcium silicates and aluminates. These silicates and aluminates are the principal components of portland cements and have hydraulic properties. The effect of typical kaolin impurities, such as MgO, FeO, ZnO, and CuO, on forming solid solutions during firing in the solid-state temperature ranges was studied.[43] This work, although theoretical and unreported in nature, should be applicable to the manufacturing of structural clay products.

A patent for producing high-brightness coating clays by a novel magnetic separation-glass bead grinding technique was awarded to the J. M. Huber Corp.[44] Another patent describing a method to remove colored titania impurities from kaolin by selective flocculation was also issued.[45] Results of laboratory and road tests showed that calcined, waterwashed, and delaminated kaolin used as an extender was either equal to or superior to talc and extended TiO_2 in three vehicle systems used in traffic paints.[46] These laboratory tests also demonstrated that calcined kaolin provided more abrasion resistance in traffic paints and was superior to all other extenders. Data on the effect of kaolin and other mineral fillers on the mechanical properties of polyester castings were added to the technical literature.[47] Fillers were used in polyesters, principally by the furniture and cultured marble industries, to achieve specific properties while reducing the volumetric cost of the casting.

A derivatographic[48] method has been developed to both identify and estimate clay minerals associated with Indian coals and permit correlating the clay content with clinkering and ashing behavior during combustion.[49] The major clay minerals and their combustion behavior were determined by combined derivatographic and X-ray diffractometric studies of both ashed and unashed coals. Detailed geological and laboratory studies of the Indian china clay deposits at Singhbhum (Bihar) and the Mayurbhanj district (Orissa) were included in Indian publications. The report on Singhbhum clays also correlated chemical analysis and physical properties with application by the domestic ceramic, textile, paper, rubber, paint, and other industries.[50] The mineralogical characteristics of the Mayurbhanj clays were stressed in a second publication.[51]

An article discussed the more important worldwide producers of clay and nonclay refractory raw materials.[52] The clay refractories discussed were the medium- and high-alumina materials of the aluminosilicate range. The nonclay materials discussion was restricted to the basic refractories; namely, magnesia types and olivine. A general introduction to the field of refractories—raw materials used, manufacturing methods, tests and specifications, end uses of the refractory products, and the general industry structure—was highlighted in another publication.[53] A detailed discussion of the U.S. refractory industry was detailed in another work.[54] A similar in-depth study of the refractory industry of the United Kingdom was also published.[55]

Thorough articles on two major domestic refractory aggregate producers, Mulcoa in Georgia and the Interpace Corp. in California, were published. The chemistry, mining, processing, and marketing of Mulcoa's entire range of refractory grogs, containing 45% to 70% Al_2O_3, were treated in one publication.[56] The other article afforded a similar exhaustive treatment of the California operation.[57] A flow diagram for producing Interpace's very pure calcined kaolin was also given. Physical and chemical properties of blast furnace stove refractories, with particular emphasis on checkers, were reviewed.[58] Zoned refractory checker settings were suggested for dome temperatures from 2,100° to 2,600°F.

A dossier on fuller's earth was published by the United Kingdom Department of Trade and Industry, collating the factural data presently available.[59] Comprehensive articles on the structure and properties of montmorillonites and attapulgite and their activated products, along with the industrial markets for attapulgite and the calcium and sodium bentonites, were published.[60] A compendium on Engelhard Minerals & Chemicals Corp's attapulgite operation, with particular emphasis on end uses, mining, and processsing, was also added to the literature.[61] A similar detailed article on International Minerals and Chemical Corp.'s southern bentonite facility was also published.[62] The use of industrial minerals, such as bentonite and attapulgite, in preparing water-and oil-base drilling fluids, along with the drilling and techniques used, was surveyed in another publication.[63]

A concise work on producing high-quality rotary kiln lightweight aggregates for block, structural, and highway surface application was published.[64] The article also compared physical test results obtained from typical lightweight aggregates with selected rigid building and highway specifications. The raw materials, clay and shale, slates, and others, used in making structural lightweight and ultra-lightweight aggregates were discussed extensively in a Government publication.[65]

Bituminous coal and lignite production increased from 552.2 million tons in 1971 to 595.4 million tons in 1972. The increase occurred primarily as a result of the increased demand for coal by electric utilities and a rebuilding of inventories which had been heavily drawn down during the negotiation of a new wage agreement late in 1971. Production from deep mines increased in all major coal producing States, while production from surface mine increased in Western States and in Alabama, Illinois, and Indiana, but declined in Ohio, Pennsylvania, and West Virginia.

The average f.o.b. mine value of coal increased from $7.07 per ton in 1971 to $7.66 per ton in 1972. The average price of coal at underground and strip mines increased from $8.87 to $9.70 per ton and from $5.19 to $5.48 per ton respectively. The average rail freight charge on coal declined from $3.70 per ton in 1971 to $3.67 per ton in 1972. The decline occurred because there were no general freight rate increases until late in the year, and unit-train traffic, which has lower per-ton-mile costs, increased nearly 14 million tons.

Consumption of bituminous coal and lignite in the United States increased 5.0% principally at electric utility and oven-coke plants. The remaining principal types of consumers used less coal than in the previous year. Consumer stock piles were replenished throughout the year and at the end of December inventories had been increased by over 21 million tons.

Employment increased from 145.7 thousand men in 1971 to 149.3 thousand in 1972. Employment in 1972 continued the upward trend since 1969 as productivity, measured by tons of output per man per day, declined for the third consecutive year. However, the amount of decline was considerably less than 1970 and 1971.

The average output per man per day at all mines fell from 18.02 tons per man per day in 1971 to 17.74 tons in 1972. At underground mines output declined from 12.03 tons to 11.91 tons while output at strip mines increased from 35.69 tons to 35.95 tons per man per day.

---

[1] Industry economist, Division of Fossil Fuels—Mineral Supply.

This chapter includes data on all bituminous coal and lignite output in the United States by operations that produced 1,000 tons or more per year. All quantity figures represent net tons of marketable coal and exclude washery and other refuse. Statistics are final and are based upon detailed annual reports of production and mine operations furnished by producers. For production not directly reported, chiefly that of small mines, data was obtained from the records of the various State mine departments, which have statutory authority to require such reports.

The monthly and weekly estimates of production, summarized in tables 4 and 9, are based upon railroad carloadings of coal reported weekly by railroads, and shipments on the Allegheny and Monongahela Rivers, reported by the U.S. Army Corps of Engineers, direct reports from mining companies, and monthly production statements compiled by certain local operators' associations and State mine departments.

DISTRIBUTION AND SHIPMENTS

Shipments of bituminous coal and lignite, summarized in tables 33 to 36, show by district of origin, State of destination, type of consumer use, and by method of transportation, the participation of coal in various local and national markets.

The distribution data by consumer use do not necessarily conform to the consumption data because the latter represents actual use at consumer facilities, whereas the distribution data represents shipments from the mines, some of which were in transit or in consumers' storage.

Total shipments increased from 553.1 million tons in 1971 to 595.2 million tons in 1972. There were large increases in shipments to electric utility and oven-coke plants. However, receipts of coal by consumers in all other industrial fuel markets and to retail dealers were down 3.6 and 1.6 million tons respectively. Miscellaneous items such as railroad fuel, mine fuel, Canadian and U.S. Great Lakes dock storage accounts, and net changes in mine inventory increased 0.9 million tons.

The distribution data are based on receipts submitted quarterly to the Bureau of Mines voluntarily by producers, sales agents, distributors, and wholesalers, who normally produce or sell 100,000 tons or more annually. The cooperation of these respondents resulted in their reporting about 93% of all coal produced or shipped. To account for total industry shipments, estimates for the remaining shipments are included, based on data from coal trade and other reliable coal statistical reporting agencies.

Additional details of bituminous coal and lignite distribution for 1972 are presented in a Bureau of Mines report.[2]

---

[2] Bureau of Mines. Bituminous Coal and Lignite Distribution, Calendar Year 1972. Mineral Industry Survey, April 9, 1973, 39 pp.

FOREIGN TRADE

In 1972 the United States exported 56.0 million tons of coal, a decrease of 0.7 million tons from that of 1971. Japan maintained its position as the principal U.S. foreign market with a 32.1% share of total U.S. coal exports. Shipments of coal to Canada, Europe, and South America accounted for 33.3%, 29.8%, and 4.8%, respectively. The slight decline in coal exports in 1972 was the result of a generally lower steel demand abroad, adequate coal stocks, and an improved world coking coal supply. The lower steel demand in Europe led to a buildup of stockpiles principally in Western Europe.

WORLD REVIEW

World production of bituminous coal and lignite in 1972 was estimated at 3,160 million tons an increase of 1.2 percent over that of the previous year. In Europe, production decreased from 1,814 million tons to 1,786 million tons. Production of bituminous coal and lignite in the U.S.S.R., the largest coal producing country in the world, was estimated at 637 million tons in 1972, an increase of 14 million tons over 1971 figures. Coal production in Asia increased 1.3% from the revised 1971 tonnage. The Peoples' Republic of China, the third largest coal-producing country in the world, increased its production from 430 million tons in 1971 to 440 million tons in 1972.

TECHNOLOGY

Major emphasis in coal research in 1972 was placed on the production of clean burning fuels from coal to help meet the Nation's rapidly increasing need for energy, while at the same time maintaining or improving the quality of the environment.

On the basis of a 2-year detailed study, the National Academy of Engineering's (NAE) Committee on Air Quality Management Ad Hoc Panel on Evaluation of Coal Gasification Technology concluded that pilot plant work on the Bureau of Mines' SYNTHANE Process should be expedited as one of the four most important American processes for converting coal to substitute natural gas (SNG). In addition NAE's Ad Hoc Panel found that the Bureau's HYDRANE hydrogasification process for SNG showed great promise and recommended further development.

The soundness of the basic design of the Bureau of Mines SYNTHANE Process was established in test operation of a 740 pounds-per-hour coal gasification pilot plant. The gasifier was operated under contract with an outside engineering firm to provide information on critical elements of the SYNTHANE Process design and to assist with the startup of the 75 ton-per-day pilot plant, for which ground breaking ceremonies were held at the Bureau's Bruceton, Pa. facilities in February 1973.

During the year bituminous coal was successfully processed in the Bureau's 10-pound-per-hour HYDRANE unit. In these tests it was confirmed that strongly caking coal could be processed without first treating the coal to destroy its caking characteristics. Because up to 95% of the methane produced results from the direct reaction of hydrogen with coal, this process offers further economic advantage over other coal gasification schemes in that a minimum amount of methanation is required to convert the gases from the gasifier to pipeline quality gas.

In other coal gasification research, strongly caking coal from the Upper Freeport seam in Preston County, W. Va., was gasified in a stirred-bed pressurized producer at 125 pounds per square inch gauge (psig), and a side stream of the gas was processed to remove up to 98% of the H_2S. This latter step was accomplished by means of a solid absorbent consisting of 25% iron oxide and 75% fly ash.

During the year, the Bureau initiated a pilot field experiment to establish the feasibility of gasifying Western subbituminous coals in place. The site for the test is near Hanna, Wyo. The coalbed is 30 feet thick and lies under 400 feet of overburden. Preliminary tests showed the need to increase the permeability of the coalbed to permit unrestricted flow of gasification gases. This was accomplished by hydrofracturing the coalbed between a specially-designed pattern of vertical boreholes. Gasification of the coal was then started by using air as the gas-making fluid. Later oxygen or oxygen-enriched air can be substituted to obtain a high-quality product gas. Underground coal gasification could provide a major source of clean energy that would significantly reduce or eliminate many of the problems associated with conventional underground mining.

Experiments were successfully concluded in a small laboratory process-development unit after showing that coal containing nearly 5% sulfur and 16% ash could be liquefied with hydrogen to yield a premium fuel oil essentially ash free and containing only 0.2% sulfur. A larger diameter reacter was constructed to study flow problems that may be encountered in scale-up of the process.

During the year construction was undertaken on a 3-stage high-temperature coal combustion pilot plant designed to produce a low-ash, high-temperature gas suitable for open-cycle magneto hydrodynamic (MHD) power generation. The design called for the gasifier combustor system to have a nominal capacity of 1,000 pounds of coal per hour and to operate at 8 atmospheres pressure. It is anticipated that the gas leaving the second stage will be at 2,300°F and have the composition of a good producer gas. The gas will be suitable for combined gas turbine-steam turbine electric power generation plant after removing particulate matter and sulfur.

Research on mine waste land reclamation emphasized work on bituminous spoil and anthracite refuse banks. In one project 5 acres of an anthracite refuse bank near Wilkes-Barre, Pa., were treated with 1,500 tons of anthracite fly ash, and then seeded with grass-legume mixture. On one-half of the treated area, about 300 tons per acre of fly ash was applied to the ground surface and mixed with surface refuse, while on the other half the fly ash was spread in a layer over the surface but not mixed. Lime was also added at the rate of 5 tons per acre to neutralize the fly ash and the anthracite refuse. In a second project, a coal company, an electric utility, and a volunteer group of concerned citizens joined to convert a coal mine refuse pile into a recreation park at Century in Barbour County, W. Va., Transformation of the waste land was accomplished through a procedure developed by Bureau researchers utilizing fly ash as a soil amendment. In a related project, two test plots on graded spoil were established in North Dakota, one at the North Beulah mine and the second at the Center mine. The first plot features a monospecies on a graded series of soils from various depths in the mining profile and tests the effectiveness of phosphate fertilizer, slack coal, and both, on vegetative viability. The second plot features mixed grass seeding on graded spoil treated with slack coal and nitrogen-phosphorus fertilizer.

Bureau personnel cooperated in a pilot plant SO_2 removal study conducted at a midwestern power and light company. The program, which lasted about 3 weeks, had as its objective determination of the amount of SO_2 that can be removed from the powerplant stack gases, using as the scrubbing medium the soluble alkali extracted with water from the ash in Montana subbituminous coal. The procedure is similar to that researched on a smaller scale at the Bureau's laboratory.

Table 1.—Salient statistics of the bituminous coal and lignite industry in the United States

Item	1968	1969	1970	1971	1972

[r] Revised.

[1] Prior to 1972 the average heat content of the annual output of bituminous coal and lignite was measured at 13,100 Btu's per pound. This value was based on an estimate made in 1949 (U.S. Bureau of Mines Information Circular 7538). In recent years this heat value has not been representative of the average unit heat value of the total annual coal supply because of the large annual increases in utilization of coal of lower heat values by the electric utility industry. The annual production values shown in this table are weighted averages of known and estimated Btu values of coal shipments to each major consuming sector. They include, for example, the Btu value of coal consumed at electric utility generating plants as reported to the Federal Power Commission and compiled by the National Coal Association. Currently, electric utility plants account for 65% of total domestic coal consumption. The averages for U.S. consumption exclude shipments overseas and to Canada, the preponderance of which is of high Btu value metallurgical coal thus accounting for the difference in values between total production and domestic consumption.

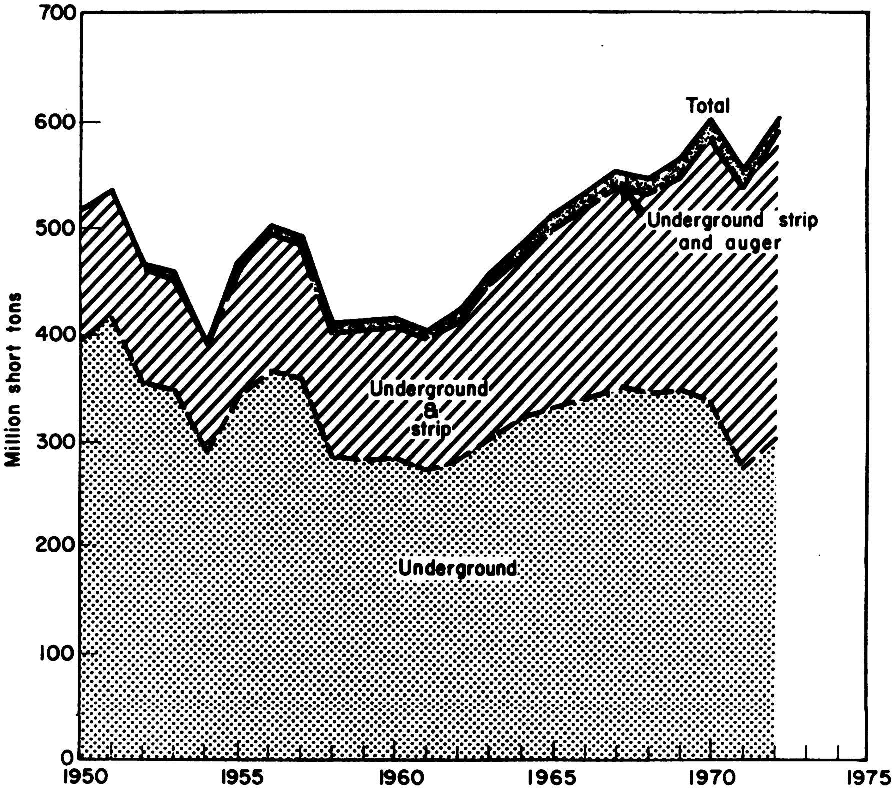

Figure 1.—Production of bituminous coal and liguite, by type of mining in the United States.

W Withheld to avoid disclosing individual company data.

[1] Includes coal loaded at mine directly into railroad cars or river barges, hauled by trucks to railroad sidings, and hauled by trucks to waterways.

[2] Includes coal used at mine for power and heat, made into beehive coke at mine, used by mine employees, used for all other purposes at mine and shipped by slurry pipeline in Arizona.

[3] Data may not add to totals shown because of independent rounding.

[4] Value received or charged for coal f.o.b. mine. Includes a value for coal not sold but used by producers, such as mine fuel and coal coked, as estimated by producers at average prices that might have been received if such coal had been sold commercially.

[5] Less than 500 tons.

Table 12.—Number of mines, men working daily, days active, and output per man per day at bituminous coal and lignite mines in the United States, in 1972, by State and county

State and county	Number of mines			Average number of men working daily				Average number of days worked			Average tons per man per day

[1] Federal Power Commission.

[2] Bureau of the Census, U.S. Department of Commerce, Ore and Coal Exchange.

[3] Estimates based upon reports collected from a selected list of representative steel and rolling mills.

[4] Estimates based upon reports collected from a selected list of representative manufacturing plants. Revised.

[5] Estimates based upon reports collected from a selected list of representative retailers. Includes some coal shipped by truck from mine to final destination. Revised.

[6] The total of classes shown approximates total consumption. The calculation of consumption from production, imports, exports, and changes in stocks is not as accurate as the "Total of classes shown" because certain significant items of stocks are not included in yearend stocks. These items are stocks on lake and tidewater docks, stocks at other intermediate storage piles between mine and consumer, and coal in transit.

Table 32.—Stocks of bituminous coal and lignite in the hands of commercial consumers and in the retail dealers' yards in the United States, 1972

Date	Total stocks (thousand short tons)	Day's supply at current rate of consumption on date of stocktaking					
		Electric power utilities	Manufacturing and mining industries			Retail dealers	Average
			Oven coke plants	Steel and rolling mills	Other manufacturing and mining industries

Tramway, conveyor, and private railroad	--	--	--	--	--	36,084
Method of movement and/or consumer uses unknown	412	−266	--	36,607	1,097	39,738
Total	412	−266	--	36,607	1,097	595,214

[1] Includes overseas exports from producing districts 13, 14, and 20.

[2] Excludes shipments to Canadian Great Lakes commercial docks and U.S. dock storage for which consumer uses are not available; however, includes vessel fuel, the destinations of which are not available.

[3] Excludes overseas exports for which consumer uses are not available.

[4] Consumer use unknown.

[5] Excludes Canada; consumer use unknown.

[6] Excludes overseas exports from producing districts 13, 14, and 20.

[1] Producing districts are defined in: Bureau of Mines Bituminous Coal and Lignite Distribution Calendar Year 1972, Mineral Industry Survey, April 9, 1973, 39 pp.

[2] Includes overseas exports.

[3] Excludes Texas.

[4] Consumer use unknown.

[5] Excludes Canada; consumer use unknown.

[6] Included with "All others."

Table 35.—Distribution of bituminous coal and lignite, in 1972, by destination and consumer use

(Thousand short tons)

Destination	Total	Electric utilities	Coke and gas plants	Retail dealers	All others [1]

[1] Less than 0.1%.

[2] A considerable block of tonnage is included under "Destinations not revealable."

[3] Includes shipments to Canadian Great Lakes commercial docks and railroad companies.

[4] Includes overseas exports from producing districts 13 and 17.

[5] Includes overseas exports from producing districts 13, 14, 17 and 20.

[6] Includes overseas exports from producing districts 13, 14 and 20.

[7] Excludes overseas exports from producing districts 13 and 17.

[8] Excludes overseas exports from producing districts 13, 14, 17 and 20.

[9] Excludes overseas exports from producing districts 13, 14 and 20.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Ecuador produces coal, but output was less than 500 tons annually in the years covered by this table.

[2] Excludes production from the state of Texas.

[3] May include a small amount of anthracite.

[4] Includes materials reported in national sources as brown coal.

[5] Available sources report only lignite production, a small amount of bituminous coal may also be produced.

[6] Revised to zero.

[7] Official sources report the aggregate of anthracite and bituminous, distribution to these separate grades is estimated from reported total.

[8] Output from Norwegian controlled portion only; in previous editions of this chapter, a separate figure (estimated) has been reported for the portion of Svalbard controlled by the U.S.S.R. This entry has been deleted inasmuch as this production is presumably included in the total output recorded for the U.S.S.R.

[9] Run of mine output.

[10] Sales, for year ended August 31 of that stated.

[11] Year beginning March 21 of that stated.

[12] Bituminous plus lignite for the People's Republic of China and Pakistan.

Coal—Pennsylvania Anthracite

By Dorothy R. Federoff [1]

Data in this chapter refer only to anthracite or hard coal, produced in 11 counties located in the northeastern part of the Commonwealth of Pennsylvania. The anthracite region is divided geologically into four fields: Northern, Eastern Middle, Western Middle, and Southern. The area is also grouped into three trade regions: Wyoming, Lehigh, and Schuylkill.

The downward trend in the production of anthracite continued in 1972. Continued losses to competitive fuels in space-heating, a labor-shortage, and hurricane Agnes, which flooded mines and slowed both production and movement to market, contributed to the decline.

Total production of anthracite in 1972 was 7.1 million short tons, a decrease of approximately 18.6% from that of 1971. Anthracite was produced at 117 underground mines, 115 strip pits, 63 culm and silt banks, and 8 dredging operations. Of the total output, 49% was produced at strip pits, 31% at culm and silt banks, 13% at underground mines, and 7% at dredging operations. Compared with tonnages produced in 1971, underground production decreased 27%; culm and silt banks, 14%; strip production, 22%; however, dredge production increased 22%.

The average value f.o.b. preparation plants for all sizes of anthracite, excluding dredge coal, was $12.40 per ton compared with $12.08 per ton in 1971. The value of pea and larger sizes showed an increase of $0.79, averaging $17.18 per ton, and the average value of buckwheat No. 1 and smaller sizes increased $0.24 per ton to an average of $10.14 per ton. However, the total value of the 1972 reduced output was $85.3 million, a decrease of 19% from the preceding year.

Apparent consumption of anthracite in the United States was approximately 5.9 million tons compared with 7.3 million tons in 1971, a drop of 19%. Although use data are incomplete for anthracite, declines occurred in all categories except coke-making, which indicated an increase of 13% for 1972. In former years, the demand for space-heating coal created a surfeit of industrial coal, but the trend has reversed—there is an increasing demand for industrial anthracite.

Data released by the U.S. Bureau of Census, indicated that 743,451 short tons of Pennsylvania anthracite were shipped to Canada and other foreign countries, compared with 671,024 shipped in 1971. A more accurate measurement of exports can be obtained by adding the quantity shipped for use by the U.S. Armed Forces in West Germany (447,728 tons), to the tonnage reported by the Bureau of Census.

Accordingly, approximately 1,191 million tons were actually exported in 1972, compared with 1,289 million tons in 1971. Increased shipments to Canada, Europe, and South America were offset by diminished shipments to Asia and other countries.

Days worked in the anthracite region averaged 216, 23 days less than in 1971. Productivity rate per man-day increased from 6.30 tons in 1971 to 6.88 tons in 1972. The number of nonfatal accidents dropped from 478 in 1971, to 272 in 1972; but the fatalities increased to 3, compared with 2 in the preceding year.

The Bureau publishes a series of weekly reports containing estimates of weekly and monthly production based on car-loadings reported by railroads, and monthly production statements of truck shipments provided by the Commonwealth of Pennsylvania.

Legislation and Government Programs.—Federal and State Government programs in the environmental area continued through 1972 and included underground mine and refuse or culm bank-fire control, surface subsidence, reclamation of old strip pits, and mine-water-control projects designed to secure the safety and livelihood of mine personnel and to protect anthracite reserves from the hazards of adjoining abandoned-mine pools and possible inundation by surface flood waters.

---

[1] Minerals specialist, Division of Fossil Fuels; Assistant Directorate—Mineral Supply.

Hydrologic studies over a period of years have provided data for evaluating mine-water problems. They involve determination of the varying heights of underground mine pools, their hydrostatic pressures and possible effect upon barrier pillars and mine dams protecting active mining operations, acid mine-water drainage into surface streams and the unconsolidated valley fill.

Close surveillance of underground mine water pool levels will be maintained to provide a data base for projected environmental protection by Federal and other Government agencies. Under the closely related mine-water control program, additional phases of the project to install a comprehensive series of mine pool monitoring stations are expected in the Western Middle and Southern fields.

A total of 39 mine-water control projects, including five Health and Safety projects, were approved during recent years. Among these projects were 17 pump projects, involving the installation of 29 large-capacity deepwell pumps, and 16 surface drainage improvement projects. Approval was given to a long-term project involving a comprehensive network of permanent mine-water pool monitoring stations throughout the anthracite region.

An overall program aimed at controlling fires in anthracite and other coal refuse banks has been developed. Efforts include investigations into the causes and environmental effects of these fires, attempts at their early detection and inventorying, and development of economic techniques for quenching and removing burning coal refuse banks. As part of the program, an aerial survey (combining conventional aerial photography with airborne infrared imagery) was taken of the burning banks in the anthracite region. The pertinent photographs, scanner imagery, and physical data obtained on the size, location, and extent of burning areas within individual banks were assembled into two compendiums designed to assist in planning for and executing extinguishment operations.

The first phase of a related demonstra-

[2] Excludes shipments to U.S. Armed Forces.

[3] Ore and Coal Exchange, Cleveland, Ohio.

tion project aimed at extinguishing and removing a burning mine and refuse bank was completed. Being tested during this initial phase was a novel technique of simultaneously quenching burning material by surface sprinklers and a subsurface water injection system. Work under this phase was judged successful in terms of the amount of water utilized in extinguishment and material removed.

Efforts have been made to encourage the development of new technology in backfilling subsurface mine voids to prevent subsidence. Investigations have been made into a system which employs a limited number of boreholes to hydraulically inject fill materials underground. The initial borehole drilling phase of a demonstration project for backfilling abandoned anthracite mine voids was completed. A sonar caliper survey of the voids intersected during drilling operations was also carried out.

A two-phase study, encompassing refuse bank removal and subsidence monitoring, was completed in the Northern Field. In the first phase, a computerized method was developed for selecting the most economic combinations of coal mine refuse sources and underground injection sites for the purpose of the removal and subsurface disposal of these wastes.

The second phase had the objective of evaluating and developing low-cost reliable instrument systems for the detection and tracing of early subsidence activity.

[1] When slate content in sizes from broken to chestnut, inclusive, is less than above standards, bone content may be increased by 1½ times the decrease in slate content under the allowable limits, but slate content specified above shall not be exceeded in any event.

A tolerance of 1% is allowed on maximum percentage of undersize and maximum percentage of ash content.

Maximum percentage of undersize is applicable only to anthracite as it is produced at preparation plant.

Slate is defined as any material that has less than 40% fixed carbon.

Bone is defined as any material that has 40% or more, but less than 75%, fixed carbon.

[2] Ash determinations are on a dry basis.

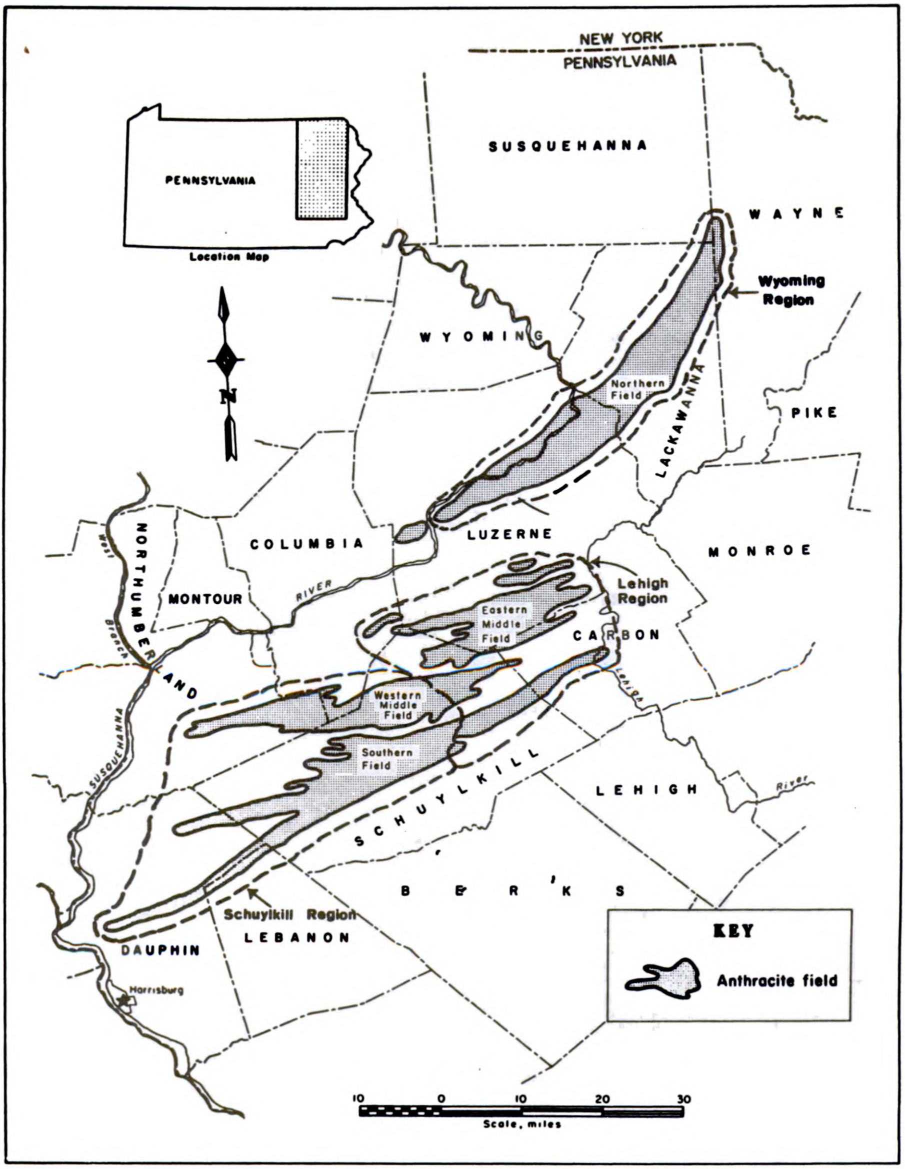

Figure 1.—Coalfields, regions, and counties of the Pennsylvania anthracite area.

DOMESTIC PRODUCTION

Production of Pennsylvania anthracite totaled 7.1 million tons in 1972, a decrease of 18.6%, or approximately 1.6 million tons less than in 1971. Underground output accounted for 13% of the total, compared with 15% in 1971; strip mining, 49% (51% in 1971); culm and silt recovery, 31% (30% in 1971); and river coal, 7% (4% in

1971). There were slight increases in the recovery of culm and silt as well as river coal—1% and 3%, respectively.

The total output by regions remained virtually at the same level as in 1971. Schuylkill region produced 57% of the total; Lehigh region, 24%; and the Wyoming region, 19%.

The two leading counties in the production of anthracite were Schuylkill County, which produced 2.9 million tons, and Luzerne County, with a production of 2.1 million tons. Other counties producing anthracite were Berks, Carbon, Columbia, Dauphin, Lackawanna, Lancaster, Northumberland, Snyder, and Sullivan.

Of total underground production, the Schuylkill region accounted for 68%; Wyoming region, 31%; and the Lehigh region 1%.

The output produced by mechanical loading of underground anthracite in 1972 declined 11%, with a decrease of 30% in loading units. Each of the two regions, Schuylkill and Wyoming, accounted for 50% of the mechanically loaded underground total. The total mechanical equipment consisted of 81 scraper loaders, 16 mobile loaders, and 46 conveyor and pit-car loaders.

Production from strip mines totaled approximately 3.5 million tons, a decrease of 22%, and accounted for 49% of the total production in 1972. Output in the Schuylkill region totaled 1,548 thousand tons, a decrease of 20%; the Lehigh region, 1,075 thousand tons, a decrease of 25%; and the Wyoming region, 860,000 tons, a decline of 23%. Of the total strip mine output, 31% was stripped in the Lehigh region, 44% in the Schuylkill region, and 25% in the Wyoming region.

Culm and silt recovery totaled 2.2 million tons, approximately 371,000 tons less than in 1971, or a decrease of 14%. Recovery by region was as follows: Lehigh region, 28% (virtually the same as in 1971); Schuylkill region, 64% (60% in 1971); and the Wyoming region, 8% (12% in 1971).

Dredging operations produced approximately 477,000 tons in 1972, an increase of 22% over that of 1971. The increase was due primarily to hurricane Agnes that flooded the region and moved fine coals and silt into rivers where it could more easily be recovered.

As the preponderant part of river coal is consumed by the producer, it is generally not as responsive to fluctuations in the general market as are the small sizes produced from other sources. Approximately 7% of the total anthracite production was dredged (4% in 1971).

In operation, at strip pits and in culm recovery in 1972, were 103 front-end loaders, 60 power shovels, and 118 draglines.

Of the total industry work force of 4,783 men in 1972, 49% were employed in the Schuylkill region, 29% in the Wyoming region, and 22% in the Lehigh region. Of total employment, 42% were employed at strip pits, 31% at preparation plants, 13% at underground workings, 7% at culm and silt banks, 6% in surface work at underground mines, and 1% on dredges. Days worked averaged 216, 23 days less than in 1971. Productivity rate per man-day increased from 6.30 tons in 1971 to 6.88 tons in 1972. The number of nonfatal accidents dropped from 478 in 1971 to 272 in 1972; however, the fatalities increased to 3 compared with 2 in the previous year.

DISTRIBUTION

Shipments of Pennsylvania anthracite reported for the coal year April 1, 1971, to March 31, 1972, totaled 7,841,827 net tons, a decrease of approximately 9% from the 1970–71 coal year. Of this amount, 83% was shipped to points within the United States, 5% to Canada, and 12% overseas. Compared with the 1970–71 coal year, shipments to American markets declined 7%; to Canada, 6%; and to foreign countries other than Canada, approximately 18%.

In the United States market, shipments of pea and larger sizes decreased by 12%; buckwheat No. 1, 18%; buckwheat No. 2 (rice), 7%; and buckwheat No. 3 (barley), 22%. However, the sizes not otherwise identified, increased 9%. In the Canadian market, pea and larger sizes dropped 18%, but the buckwheat No. 1 and smaller sizes, indicated a decline of only 2%. Exports to countries other than Canada, showed a decline in pea and larger, and buckwheat No. 1 and smaller sizes—14% and 26%, respectively.

All market areas in the United States indicated continued losses with the exception of the "Other States" category, which showed an increase of 6%. Shipments to the New England area were 15% below the 1970–71 coal year level; the Middle Atlantic area declined 6%; and the South Atlantic and Lake States dropped 23% and 27%, respectively.

CONSUMPTION AND USES

Apparent domestic consumption of anthracite in 1972 (production minus exports and shipments to U.S. Armed Forces, West Germany), was 5.9 million net tons, compared with 7.3 million tons in 1971. A diminishing market for space-heating anthracite and decreasing consumption at electric utilities contributed to the decline.

Overall consumption of anthracite was as follows: space-heating, 50%; electric utilities, 27%; and the remaining 23% divided among other industrial users. Although use data are incomplete for anthracite, declines occurred in all categories except coke-making, which indicated an increase of 13% over 1971.

The Federal Government continued to supplement the fuel needs of the U.S. Armed Forces in West Germany with purchases of anthracite. Shipments in 1972 were approximately 448,000 tons compared with 718,000 tons in 1971, a decrease of 38%.

STOCKS

Monthly data on stocks held in retail yards indicated an inventory of 123,000 tons, at yearend 1972, a decrease of 32.4% from January 1, 1972.

The electric utilities reported a decrease of 20.3% in their inventory—895,000 tons at yearend 1972, compared with yearend stocks of 1,123,000 tons in 1971.

Stocks at coke plants totaled 84,000 tons at the end of the year, a decrease of 28.8% from the beginning of the year.

Stocks at the Upper Lake docks (Lake Superior and Lake Michigan) dropped from 1,000 tons at yearend 1971 to less than 500 tons at yearend 1972.

PRICES AND SPECIFICATIONS

The average value of Pennsylvania anthracite production in 1972 was $12.00 per ton compared with $11.86 per ton in 1971. The slight increase was due to a greater demand for industrial sizes which have a lower market value. Total value of production in 1972 was $85,250,862, compared with $103,469,207 in 1971.

The average value per ton of the larger groups of sizes was $17.18 f.o.b. preparation plants, an increase of $0.79. Price increases per ton for these larger sizes—egg, stove, chestnut, pea—were $0.35, $1.08, $0.87, and $0.44, respectively. The average value per ton of the smaller sizes increased $0.24, to $10.14 per ton. The individual prices of smaller sizes were as follows: Buckwheat No. 1, $15.38 (increase of $0.55; buckwheat No. 2 (rice), $15.12 (increase of $0.56; buckwheat No. 3 (barley), $12.97 (increase of $0.41); buckwheat No. 4, $9.11 (increase of $1.04); buckwheat No. 5, $6.03 (decrease of $0.05); and other, $5.15 (increase of $0.71). All the above prices exclude dredge coal.

Average wholesale prices as quoted in the Black Diamond magazine were as follows: Egg and stove, $18.25 to $19.75; chestnut, $18.00 to $19.50; pea, $16.00 to $17.50; buckwheat No. 1, $16.00 to $17.50; buckwheat No. 2 (rice), $16.00 to $17.50; and buckwheat No. 3 (barley), $15.00 to $16.50.

FOREIGN TRADE

Data released by the Bureau of the Census, U.S. Department of Commerce, indicate that 743,451 net tons of Pennsylvania anthracite were exported in 1972, an increase of approximately 11% over 1971 exports. However, this does not fully reflect the movement of anthracite to the Continent, because the Bureau of Census does not include in its figures coal shipped abroad for the use of U.S. Armed Forces in West Germany. A more accurate measure of the export trade can be obtained, therefore, by adding the military tonnage to the Bureau of Census data. Shipments to the U.S. Armed Forces in 1972, totaled approximately 448,000 net tons as compared to the 718,000 net tons shipped in 1971, a decrease of approximately 38%.

Increased shipments to the European, Canadian, and South American markets were offset by decreased export tonnages to Asia and other countries—consequently, the net result was a decrease in total exports of anthracite in 1972 of approximately 198,000 net tons, or 14% below the 1971 level.

WORLD REVIEW

Precise data are not available from all anthracite producing countries. Some of the figures are only estimates while other countries include in their official data fuels which, by U.S. standards, are of no higher quality than semianthracite. Despite these inadequacies, information, when compared with data from similar sources for previous years, is sufficiently accurate to indicate general trends. Based on such information, and in full recognition of the margin of error that could exist, it is indicated that total world production of anthracite in 1972 (approximately 195.9 million short tons) showed a slight decrease of 1.4% from that in 1971.

Anthracite production generally reflects the demand. The ready availability of alternative and more convenient fuels at competitive prices is considered to be the principle reason for the lessening demand for anthracite in world fuel markets.

The People's Republic of China, North Korea, and the U.S.S.R. produced approximately 70% of the total world production, a slight increase of 3.5% over that in 1971. Preparation plants of the Ministry of the Coal Industry in the U.S.S.R. processed approximately 35,588,000 short tons of large and medium-size classification anthracite in 1972.

Imports of anthracite to Japan for 1972 totaled 833,000 short tons, compared with 1,746,000 tons for the same period in 1971. The People's Republic of China, South Korea, and Canada were principal sources, with total shipments of 585,000 short tons, or 70% of the total imported. Imports from North Vietnam continued to reflect the effects of the shipping blockade which reduced anthracite shipments to 74,000 short tons compared with 452,000 tons shipped to Japan in 1971. Until the suspension of shipments in May, 1972, Hongai coal accounted for most of Japan's imports of anthracite.

The Republic of South Africa's reduced demand and reversals in foreign trade contributed to the sharp drop in the production of anthracite in 1972. Output for the year totaled 1,473,000 short tons compared with 2,029,000 short tons in 1971. Of that total, 521,000 tons was consumed in the domestic market, and the remainder was exported to Japan and to Europe.

As the production of coal in Italy is minimal, there are no exports. Imports of anthracite from the United States increased from 229 short tons in 1971, to 32,000 tons in 1972. The U.S.S.R.'s trade in the first half of 1972 was characterized by sharply reduced anthracite deliveries to Italy which dropped from 95,000 tons in 1971, to 32,000 short tons in 1972.

Belgium's coal supply in 1972 was characterized by a drop in production and a sharp increase in consumption which required greater imports to close the gap between indigenous production and internal demand. The production of anthracite (up to 14% volatility), amounting to 3.3 million short tons, was almost 457,000 tons below the 1971 output. Belgium's exports in 1972 maintained the downward trend that characterized the trade in recent years. Virtually all of the export shipments went to member Community countries headed by West Germany.

TECHNOLOGY

The scientists and the engineers of the National Coal Board have developed a new unique process of obtaining active carbon from anthracite at a much cheaper rate.[2]

The new principle uses a fluidized bed steam activation process which utilizes the full advantage of anthracite's low-volatile content to obtain a higher yield of the final product than was previously possible with conventional activation processes.

Sized anthracite is fluidized with hot gas and then activated by injecting superheated steam into the reactor. While undergoing processing, the internal surface area of the carbon particles increased to approximately 30 times the untreated size. The active carbon is cooled, screened into different sizes and is then ready for collection for sale. Continuous control testing is carried on during manufacture to ensure that activity levels are maintained in the product to a consistently high standard.

One of the main uses of active carbon is in the treatment of potable water supplies for the removal of residual taste, odor, and color. In comparison to other filtration agents, active carbon is the best to absorb all those unwanted elements in water to make it safe for drinking purposes.

Anthracite has been used for several years for water filtration purposes but only in relatively small quantities as it was difficult to convert anthracite directly to active carbon.

Because of the sulfur limitations imposed by air-pollution-control regulations, the continuous availability of metallurgical-grade coking coals is becoming a matter of increasing concern to the iron and steel industry and other consumers of coke as other consuming sectors are using greater quantities of these low-sulfur coals in order to conform to the sulfur limitations. Anthracite, with its low sulfur content when combined with other chemical constituents used to produce foundry coke gives strength and stability to the coke. As a result, increasing quantities of anthracite may be used for the production of coke in the future.

Some fundamental research has been conducted by the Bureau to develop new uses for anthracite: Studies have been made of its mineral content and chemical constituents; experiments were conducted on its conversion to gas and its use in coke manufacture; and studies were made of the utilization of ash resulting from the combustion of anthracite. Such research is continuing at a modest level to improve anthracite utilization generally, including its use in industrial and commercial processes. Considering the present status of the industry, however, and the continuing decline in demand, the amount of research devoted to new uses, markets, and opportunities for anthracite is relatively limited.

The program initiated in 1962 by the Bureau to microfilm all available data relating to abandoned anthracite mines was continued during the year. Maps, cross sections, and other related data were recorded for future studies of subsidence, mine fire control, and for evaluating building sites. The data accumulated by the program also has proved to be an invaluable aid in evaluations made by the U.S. Army Corps of Engineers for maintenance and possible expansion of flood control projects under its jurisdiction in the northern anthracite field. The time available for project work in 1972 was severely limited because of work assignments resulting from the flood, particularly in map work related to subsidence, mine water, and levee studies. To date, a grand total of 9,046 mine and folio maps, comprising 24,435 frames, have been photographed.

[9] Estimated from reports submitted by a selected list of retail dealers located outside the producing region.
[10] Furnished by the Bureau of Labor Statistics from data obtained from authorized trade publications.

NOTE: According to the Association of American Railroads, 697,092 short tons of anthracite were exported to Europe during 1972 compared with 904,948 short tons for 1971. Of this total 464,680 short tons were consigned to West Germany and the Netherlands including exports to the U.S. military forces. This compares with 748,996 short tons for 1971.

Vietnam, North [e]	3,300	3,300	2,200
Total	198,664	198,653	195,933

[e] Estimate. [p] Preliminary. [r] Revised.

[1] An unspecified amount of semianthracite is included in figures for some countries.

[2] In addition to the countries listed, Canada, Colombia, New Zealand and South Vietnam produce anthracite, but the level of production is not reported and available information is inadequate to make reliable estimates; in Colombia output may total 100,000 tons annually, while in New Zealand and South Vietnam, output is insignificant.

Cobalt

By John D. Corrick [1]

Cobalt consumption increased 13% in 1972 compared with that of 1971; this was the first increase in consumption since 1969. Demand for cobalt at the beginning of 1972 was depressed; however, a progressive improvement in demand occurred during the second half of 1972. Consumer stocks, which had reached their lowest level in 5 years during 1971, remained at a low, but relatively stable, level during 1972. Government sales of cobalt from the strategic stockpile were a significant source of supply during 1972 with over 8.6 million pounds sold.

Legislation and Government Programs.—General Services Administration (GSA) continued to offer specification-grade and subspecification-grade (Calera material) cobalt metal in various forms for sale during 1972. Sales were on an unrestricted-bid basis except that total sales of specification-grade material were limited to approximately 1 million pounds per month and 500,000 pounds per bidder per month. Government sales of cobalt for the year totaled 8,629,692 pounds, compared with 901,699 pounds sold in 1971. Of the quantity sold, 5,015,061 pounds was subspecification Calera cobalt, GSA's entire Calera stock.

As of December 13, 1972, total U.S. Government stockpile inventory was 71,499,318 pounds of cobalt. Of this quantity, 67,913,260 pounds was stockpile grade.

DOMESTIC PRODUCTION

Domestic production of cobalt-bearing pyrite concentrates was discontinued at the end of 1971, shutting off the only source of domestically mined cobalt. Professional Oil and Management Co. (POM Corp.) and The Hanna Mining Co. agreed to explore and possibly develop the Iron Creek copper-cobalt prospect located in the Salmon-Blackbird mining district of Idaho. The prospect was owned by POM's subsidiary, Sachem Prospects Corp.[2] At yearend, the company had driven 615 feet of underground openings, built 500 feet of bulldozer roads, and taken approximately 1,000 feet of core samples.

American Metals Climax Inc. (AMAX), through a new division, AMAX Nickel, continued rehabilitation of its Port Nickel, La., refinery. Late in 1972 the company acquired additional acreage which doubled the amount previously owned and increased river frontage from 1,800 to 3,600 feet.[3] Tentatively the refinery will begin processing material from the Botswana Bamangwato Concessions nickel-copper project in 1974. In addition to nickel, the refinery will produce cobalt from other feed materials acquired by AMAX.

CONSUMPTION AND USES

Consumption of cobalt in the United States in 1972 was 13% above that in 1971 and reversed a declining trend that began in 1970. Increased consumption could be related to improved economic activity around the world, particularly the demand for cobalt in superalloys and magnetic alloys. Major uses of cobalt in 1972, as shown in table 4, were in magnetic alloys, superalloys, salts and driers, and cutting and wear-resistant materials. Data reported by consumers showed that of the cobalt consumed in the United States during 1972, 74% was as metal, 19% was as salts and driers, 5% was as oxide, and 1% was as purchased scrap. Total U.S. cobalt consumption was 14.1 million pounds in 1972.

Officials of Varian Associates announced commercial production of samarium-cobalt magnets through the use of powder metallurgy techniques. The magnets were to be produced in the form of rings, rods, bars, rectangles, and sections for use in microwave tubes, electric watches, motors and generators, solid state devices, and instruments. Researchers at Varian investigated other rare-earth cobalt alloys which showed even greater promise than samarium-cobalt. Among those alloys tested were praseodymium-cobalt and misch-metal cobalt.[4]

Numerous new cobalt alloys were introduced in 1972. E. I. du Pont de Nemours & Co., Inc. introduced a novel group of patented, high-temperature cobalt-based alloys with superior wear and friction resistance.[5] These intermetallic materials were designed for high-temperature applications where lubrication was a problem. The alloys were composed of cobalt, molybdenum, and silicon and were available in powder form for plasma spray applications and hard surfacing, and as irregularly shaped powders for powder metallurgy usage. The Huntington Alloy Products Division of the International Nickel Co. (INCO) introduced a new nickel-based heat-resisting alloy containing 12.5% cobalt and designated Inconel 617.[6] The alloy was developed for use in gas turbines exposed to high temperatures and was reported to have excellent resistance to oxidation and carburization at 1,095°C.

PRICES

The producer price for cobalt metal in the form of granules (shot) or broken cathodes in 551-pound (250-kilogram) drums remained at $2.45 per pound, f.o.b. New York or Chicago, throughout the year.

Sales of cobalt metal by the Government on a "sealed-bid" basis ranged in price from $2.15 to $2.41 per pound for specification-grade material and from $1.92 to $2.15 per pound for subspecification-grade material. All prices were f.o.b. carrier's conveyance at Government storage locations.

FOREIGN TRADE

Exports of unwrought cobalt metal and alloys and of waste and scrap totaled 2,148,261 pounds, gross weight, having a value of $3,168,899, and went to 17 countries. Japan and West Germany received the greater part, 1,164,710 pounds ($1,358,131) and 550,933 pounds ($1,115,547), respectively. Exports of wrought cobalt metal and alloys, 448,844 pounds, gross weight, having a value of $1,836,158, went to 19 countries. The imports of cobalt salts and compounds given in table 7 came principally from France and the United Kingdom.

WORLD REVIEW

Cobalt produced in the free world in 1972 was sufficient to meet demand. Zaire led all countries in mine production of cobalt and accounted for 56% of the total world output. Nevertheless, cobalt metal production decreased in Zaire, Zambia, Canada, West Germany, and Finland in 1972 compared with that of 1971. Reasons for decreased production were varied and ranged from Zaire's reducing production in order to bring the supply-demand relationship into better balance to West Germany's difficulties in securing adequate supplies of raw materials.

Australia.—Construction work began in 1972 on the Freeport Minerals Co. Greenvale nickel-cobalt project in Queensland, Australia. The Greenvale project was a 50–50 joint venture between Metals Exploration N.L. and Freeport Minerals Co. Freeport, which held a 22% equity interest in Metals Exploration, holds a total interest of approximately 61% in the project. The Ralph M. Parsons Co. of the United States was contracted to design and construct processing facilities at Townsville, Australia, to treat the Greenvale laterite ore. The plant will treat annually approximately 2.3 million tons of dry ore and produce about 46 million pounds of nickel and 2.75 million pounds of cobalt in the form of nickel-cobalt sulfide. A group of five Japanese companies reportedly will purchase all of the nickel-cobalt sulfide produced for the life of the mine. Production was scheduled for 1974.

Canada.—Mine production of cobalt decreased in 1972 by 4% compared with that of 1971. INCO's deliveries of cobalt were 2,210,000 pounds in 1972, compared with 1,980,000 pounds in 1971 and 1,870,000 pounds in 1970. Cobalt production at the Falconbridge Nickel Mines Ltd. refinery in Kristiansand, Norway, was halted when a fire in May killed three workers and seriously damaged the refinery. Inventories of refined cobalt were exhausted early in 1972. Reportedly, Falconbridge's new refinery in Norway was to begin producing cobalt in March 1973. A newly formed European subsidiary of Falconbridge, Falconbridge Europe S.A., took over the

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available. W Withheld to avoid disclosing individual company confidential data.

[1] In addition to the countries listed, Bulgaria, Cyprus, East Germany, New Caledonia, Norway, Poland, Spain and Sweden are known to produce ores (copper, nickel, and/or pyrite) that contain recoverable quantities of cobalt, but available information is inadequate to make reliable estimates of output levels. Other nations may also produce cobalt as a byproduct component of ores and concentrates of other metals.

[2] The United Kingdom recovers cobalt metal from intermediate metallurgical products imported from Canada, but data on output is inseparable from the total reported by Canadian producers. Czechoslovakia presumably recovers cobalt from materials imported from Cuba but data are inadequate to estimate output. Belgium and Japan, which import substantial quantities of crude materials containing cobalt, have not recorded output in recent years, but may be producing metal and/or cobalt compounds. Poland apparently processes cobalt-bearing copper ores but no data on cobalt recovery are available.

[3] Actual mine output not reported. Data presented for mine output are total cobalt content of all products, including nickel oxide sinter shipped to United Kingdom and nickel-copper matte shipped to Norway for further processing. Data presented for metal content are total cobalt content of all products less cobalt output recorded for Norway, thus the metal data include cobalt content of oxides and other compounds that are not reduced to metal as well as total metal actually recovered in Canada and the United Kingdom.

[4] Domestic mine output, if any, is negligible.

[5] Produced entirely from nickel-copper matte imported from Canada; domestic mine output is recovered abroad.

[6] Insufficient data are available to permit separate estimates of mine and metal production.

[7] Metal figures given are content of matte.

sale of cobalt and nickel in Belgium, the Netherlands, and Spain from Brandeis Goldschmidt in 1972. Falconbridge continued to make progress on the construction of the Becancour, Quebec, refinery complex. When completed in 1975, the refinery will produce 500,000 pounds per year of high-purity cobalt salts. Sherritt Gordon Mines Ltd. reportedly had a refinery output of cobalt in 1972 of 809,000 pounds compared with 561,000 pounds in 1971. Sales of cobalt for the 2 years were 713,000 and 679,000 pounds, respectively. Officials of Sherritt Gordon reported the successful completion of tests at its Fort Saskatchewan demonstration plant on laterite ore from Gag Island, Indonesia for P. T. Pacific Nickel Indonesia in 1972. A detailed feasibility study on mining and processing facilities to produce over 100 million pounds of nickel and approximately 4 million pounds of cobalt per year was to be completed in the fourth quarter of 1972. Officials of Dickerson Mines of Canada reported the shutdown of its cobalt refining operation in February 1972. The refinery reportedly had problems obtaining raw materials during its 10 years of operation. The company's inventory of cobalt, silver, gold, and copper at the refinery was liquidated early in 1971.

Finland.—Officials of Outokumpu Oy reported continued progress on the development of the Vuonos mine. Concentration of nickel ore from the Vuonos mine began in late 1971. When in full operation the mine will produce 72,000 tons per year of cobalt-rich iron pyrites. Cobalt metal production was 885 tons in 1972, compared with 1,020 tons in 1971.

India.—Recent discoveries of nickel-cobalt ore bodies in the State of Orissa prompted the National Metallurgical Laboratory at Jamshedpur to develop a suitable process for treating serpentinous and lateritic nickeliferous ores. The process involved a roast-reduction step followed by ammoniacal leaching. Commercial feasibility of the developed process would require a nickel recovery of 60% from an ore containing over 0.41% nickel. The Sukinda nickel deposit in Orissa was estimated to contain 14 million tons of nickel laterite ore grading 0.8 to 1.4% nickel.

Indonesia.—P. T. Pacific Nickel Indonesia received a favorable report from tests performed at Sherritt Gordon's Fort Saskatchewan plant on laterite ore from Gag Island. Detailed feasibility studies on mining and processing facilities were to be completed in late 1972 by Sherritt Gordon for P. T. Pacific, in which Sherritt had a 10% interest.

Officials of INCO reported signing participation and sales agreements with six Japanese firms covering its nickel project on the Indonesian island of Sulawesi. INCO's subsidiary, P. T. International Nickel Indonesia, was to control 60% with the remaining 40% divided evenly between Japanese firms and Indonesians. Initial production capacity was rated at over 15,000 tons of nickel plus cobalt per year in the form of a 75% nickel matte.

Philippines.—Despite devastating floods which took a heavy toll of life and property in the Philippines in 1972, work progressed satisfactorily on construction of Marinduque Mining and Industrial Corp.'s nickel refinery on Nonoc Island. Bechtel Corp. and Bechtel Overseas Corp. were providing engineering, procurement, and construction management services for the project. When completed in July 1974, the project will produce 3.3 million pounds of cobalt per year in the form of mixed sulfides along with nickel briquets and powder. Overseas Private Investment Corp. pledged to guarantee $17 million in U.S. loans for the $232.5 million project. The value of U.S. equipment and services for the project was estimated at over $60 million. By mid-1972, Marinduque had placed a $1.9 million order with Sumitomo Shipbuilding and Machinery Co. for eight electrostatic precipitators and four dust collectors. Sumitomo was licensed by Joy Manufacturing Co. of the United States to build Joy-designed dust collectors for Asian markets. Delivery of equipment was slated for spring 1973. At yearend, officials of Marinduque announced a $3 million sale of stock, thereby completing its $8 million equity share of the $232.5 million project. Sherritt Gordon was to buy $6.8 million of Marinduque stock, an increase of $1.8 million over the original amount Sherritt agreed to buy.

Sumitomo Metal Mining Co., Ltd., Nippon Mining Co., Ltd., Pacific Metals Co., and Nissho-Iwai Co. of Japan continued negotiating with Soriano Co. of the Philippines for development of nickel-cobalt deposits on Palawan Island. The ore was offered the consortium by Rio Tuba Nickel Mining Corp. of the Philippines. The Japanese were requested to finance 80% of the project's cost. If negotiations succeed, it was estimated that 1 million tons of ore per year would be mined beginning about 1976.

Uganda.—Reduced mine production by Kilembe Copper Cobalt Ltd. in 1972 could be traced to labor unrest resulting from expulsion of technicians by the Government and uncertain copper markets. Kilembe reportedly was "down to the bone" staff-wise. The company requested the Ugandan Government to grant tax reliefs, which if not granted would decrease exploration work and thereby reduce reserves. Probable ore reserves did decrease by about 1.1 million tons in 1971 with little additional probable ore outlined. A cobalt bearing pyrite concentrate was produced and stockpiled at the mine during 1972.

Zaire.—La Générale des Carrières et Mines du Zaïre (GECAMINES), the state holding company for all extractive metallurgy activities in Zaire, through its operating company La Générale Congolaise des Minerais (GÉCOMIN) was again the leading world producer of cobalt, accounting for 56% of the total world mine output. Cobalt production came from the Province of Shaba, formerly known as Kinshasa. Principal producing mines were the western group, comprised of the underground Kamoto and the open pits of Kamoto, Musonoi, and Ruwe; and the central group, comprised of the underground Kambove and the open pits of Sesa and Kakanda. The Luilu refinery treated ore from the western group of mines, while the Shituru plant treated ore from the central group of mines. A new mill at the Musonoi mine began trial operations in mid-July and became operational in October.

As a result of depressed world cobalt markets in 1971, about 3,500 tons of cobalt had been stockpiled by yearend 1971. New ore reserves in Shaba were reported by officials of GECAMINES as 32.4 million tons containing 190,948 tons of recoverable cobalt and 852,212 tons of recoverable copper.

Japanese interests and the Government of Zaire were negotiating for the construction of approximately 550 miles of rail line to fill gaps in the present rail system and provide an unbroken line from Shaba to the Atlantic Ocean, a distance of 1,240 miles. Ore shipments in Zaire presently must travel a complicated route of jungle river boats and primitive rail lines, taking from 30 to 40 days to reach the Atlantic coast. The new rail lines would cut shipping time to approximately 3 days. Decreased shipping time reportedly would allow the quantity of exported ore to be increased from 500,000 tons per year to about 800,000 tons per year by 1980.

Société Minière de Tenke-Fungurume, in which Standard Oil Co. (Indiana) held a 28% interest, completed 220 test boreholes representing 25,126 meters of diamond drilling in the Tenke-Fungurume district of Zaire. Assays on material from 168 of these holes delineated probable and indicated ore reserves of 20 million tons grading 6.2% copper and 0.4% cobalt. Inferred reserves were estimated at 14.8 million tons.

Zambia.—Nchanga Consolidated Copper Mines Ltd. (NCCM) began installation of commercial-scale carbon columns at its Rokana cobalt plant in 1972. The company was prompted to install the columns after successfully operating pilot-sized columns for 2 years. The pilot columns were capable of removing up to 80% of the contained sulfur with a resulting increase in capacity of 2%.

Roan Consolidated Mines Ltd. (RCM) planned on doubling output of its Chambishi mine by initiating underground operations. RCM awarded a $40 million contract to the British firm of Balfour Bealty and Co. to conduct the necessary civil and mechanical engineering and construction work at Chambishi. The contract will involve extensions to metallurgical buildings, installation of ore crushing and flotation equipment, head frame and hoisting equipment, rail extensions, and construction of permanent living quarters for workers.

Zambia's two mining companies, NCCM and RCM, approved capital expenditures of $663 million during 1972–76 for maintaining and expanding current production of copper and cobalt. These expenditures fall under Zambia's second 5-year national development plan. At yearend, Zambia was successful in lining up loans from foreign countries to cover part of the expenditures. The Government, acting through the state-run Mining and Industrial Development Corp., was setting up a new central committee to supervise the nationalization of the copper-cobalt industry. The stated objectives of centralization were to achieve the optimum rate of nationalization, to rationalize training activities, and to develop industry manpower plans.

TECHNOLOGY

Bureau of Mines scientists reported the use of a cobalt-molybdate catalyst to remove over 90% of the nitrogen and sulfur compounds from shale oil. The catalyst was used in the initial hydrogenation step of a process to convert oil shale to gasoline having an octane rating of 89. The researchers found that a pressure of 200 pounds per square inch and a temperature of 900°F were preferred if optimum amounts of gasoline were to be produced.

Interest was maintained during the year on the development of high-strength magnets formed by alloying cobalt with various rare-earth metals. Scientists from General Electric Co. successfully increased the maximum energy product of the company's rare earth-cobalt permanent magnets by 10% to 25 million gauss-oersteds.[7] Bureau of Mines' scientists continued their investigations into the properties of praseodymium-cobalt magnets during 1972. Researchers at Tohoku University in Japan demonstrated that ductile permanent magnets composed of iron, chromium, cobalt, and molybdenum exhibited a maximum energy product of 5 million gauss-oersteds after appropriate heat treatment. The discovery was significant in that the lower cost ductile alloy's energy product was exceeded only by that of the more expensive cobalt-platinum magnets.[8]

General Magnaplate Corp. of Linden, N.J., announced the development of a coating process whereby nickel and cobalt metals were electroplated to the surfaces of powdered metal parts. The new technique reportedly gave gears a tough, nonporous surface with permanent lubricity and abrasion and corrosion resistance under severe temperature, atmospheric, and load conditions.[9]

---

[7] Work cited in footnote 6.
[8] Work cited in footnote 6.

The State University of New York reported development of an antithrombogenic cobalt-chromium alloy. The alloy, in the form of tubes and valves, was tested as cardiovascular implants in dogs. Because of the alloy's resistance to corrosion in biological fluids, it was reported to have great potential in cardiovascular prostheses.[10]

Numerous technological innovations were reported in the formation of cobalt alloys in 1972. General Electric Co. was granted a U.S. patent covering a high-temperature, oxidation- and corrosion-resisting cobalt-based alloy having improved strength and ductility. The new alloy (FSX-430) was claimed to have greater high-temperature ductility, creep-rupture strength, and oxidation resistance while maintaining the high-temperature tensile strength and hot corrosion resistance of its predecessors.[11] INCO developed a cast heat-resistant nickel-base alloy (IN-643) containing 12% cobalt for use over extended periods under high stress and at temperatures up to 1,150°C.

A large number of patents were issued both in the United States and abroad, ranging from extractive metallurgy through smelting technology to the formation of new cobalt alloys. Technical papers were presented on unalloyed and alloyed cobalt systems, heat-resisting alloys, magnetic materials, tool and wear-resisting materials, cast irons and alloy systems, films and coatings, nonmetallic uses of cobalt, and analytical techniques.[12]

Coke and Coal Chemicals

By Eugene T. Sheridan [1]

Production of coal coke in the United States in 1972 was about 5% greater than in 1971. The increased output was attributed partially to the fact that coke plants operated continuously throughout the year whereas, in 1971, operations were curtailed by labor strikes in both the steel and bituminous coal industries. Part of the increase was the result of greater demand for coke by blast furnaces, which increased their output of pig iron and ferroalloys in 1972 by nearly 10%.

Production, which averaged 5.0 million tons per month, remained relatively stable throughout the year. The average output per day for all plants ranged from a low of 155,000 tons in January to a high of 172,000 tons in April, with daily output for the year averaging 165,000 tons.

Demand for coke exceeded production during most of the year and producers month-end stocks of oven coke were 16% lower at the end of the year than when the year began. Stocks on hand at oven-coke plants at the end of 1972 were equivalent to 18 days' production at the December rate of output.

Blast furnaces continued to use the bulk of the Nation's coke production, receiving 92% of the 61.1 million tons of coke distributed by producers. However, consumption of coke per ton of hot metal produced at blast furnaces decreased, because of a significant increase in the quantities of fuel oil, tar, and pitch used as supplemental fuels in blast furnaces.

Breeze production increased 5%, mainly because more coal was carbonized. Breeze is unsuitable for most metallurgical applications because of its small size and high ash content, the larger part of the breeze production is used by producers for sintering iron ores and other industrial purposes. However, 50% of the 1972 output was sold, mainly for use as a reductant in electric furnaces that smelt phosphate rock to produce elemental phosphorus. Sales of breeze in 1972 were 13% greater than in 1971.

Coal costs increased substantially in 1972. The average delivered value of coking coals carbonized at oven-coke plants increased $1.73 per ton, while the value of coking coals carbonized at beehive plants increased $1.31 per ton. Price increases were reported by plants in all States except Minnesota and Wisconsin; the largest increases were noted for the coals received by plants in Kentucky, Missouri, Tennessee, and Texas.

Production of coke-oven gas increased 6% because of a higher yield and because more coal was carbonized. Output of ammonia, crude tar, and crude light oil increased also, for the same reasons.

Coke prices increased again during 1972. The average value of $40.70 per ton received by producers for all grades of oven coke and $22.04 per ton for all grades of beehive coke represented respective price increases of 9% and 3%. The average value of blast-furnace coke remained at about the level of 1971. The unit value of foundry and other industrial coke, however, increased 7% and 24%, respectively.

Foreign trade in coke was relatively small; exports amounted to only about 2% of the production. The bulk of the coke exported was shipped to Canada, West Germany, Mexico, the Netherlands, and Spain. Exports declined 18% from the 1971 level.

The total value of all coals carbonized was $1,374 million, and the total value of all products of carbonization was $2,375 million. The combined value of coke and breeze, the principal products, accounted for 88% of the total value of all products.

COKE AND BREEZE

DOMESTIC PRODUCTION

Recovering from the effects of labor strikes that curtailed production during the latter part of 1971, production assumed more normal levels during 1972 and output for the year was 5% greater than in 1971. Monthly production varied between 4.7 million and 5.3 million tons, with the largest output recorded in May. Daily output for the year averaged 165,000 tons, up 5% from the 157,000 tons per day recorded during 1971. These data are shown in table 5.

Ninety-one percent of the oven coke in 1972 was produced at furnace plants. These are plants that are owned by, or financially affiliated with, iron and steel companies and are operated mainly to produce coke for use in their blast furnaces. The remaining oven coke was produced by merchant plants, which is the segment of the industry that produces various grades of coke for sale on the open market. There were 48 furnace plants and 14 merchant plants in operation throughout the year. Current annual and monthly outputs of these plants are shown in tables 6 and 7.

Coke was produced in 18 States in 1972. The relative amounts of coke produced in the various States have changed little in the past decade, except that Connecticut and Massachusetts have ceased to be producing States and production was discontinued in New Jersey in 1971. Because coke is used principally for blast furnace fuel, the coke industry is concentrated in the major steel-producing areas of the Eastern and North Central States. The bulk of the 1972 coke output was produced in 14 States east of the Mississippi River. About 4 million tons, 7% of the total, was produced in States west of the Mississippi River.

Pennsylvania, the largest producer, accounted for 27% of the output and was followed by Indiana, Ohio, Alabama, and Michigan, in the order named. The combined output of these five States was nearly three-fourths of the national total. These data are shown in table 8.

An average of 1,476 pounds of coke was produced for each ton of coal carbonized in the United States in 1972. The 1972 yield of coke from coal, which averaged 68.96% has remained fairly constant during the past decade.

Breeze is the term applied to the small sizes of coke that result from screening. Although there is no designated size, breeze refers generally to coke that passes through a ½-inch screen. Coke producers currently consume 53% of the breeze produced, principally as a fuel in agglomerating plants. The remainder is sold, mainly for use as a fuel for smelting phosphate rock to produce elemental phosphorus. The amount of breeze sold has increased significantly in recent years and in 1972, nearly, 50% of the quantity produced was sold.

The breeze yield varies according to operating practices and the quality of the coals carbonized. The lowest yield, 3.4%, was recorded for Pennsylvania, while the yield for Indiana averaged 6.5%. The national average yield of 4.9% in 1972 has not varied significantly during the past decade.

An average of 98.4 pounds of breeze was produced for each ton of coal carbonized at oven-coke plants in 1972. Breeze yields of beehive-coke plants were substantially higher than those of oven plants, but beehive breeze production was negligible because only a few plants had recovery facilities.

Production and disposal of breeze, by State, in 1972 are shown in table 9. Table 10 shows the quantities consumed by producers for various uses and the quantities sold during the past 5 years.

CONSUMPTION AND SALES

Consumption of coke in the United States in 1972 totaled 60 million tons. This quantity (domestic production plus imports, minus exports and changes in stocks) was about 3 million tons more than that consumed in 1971 and the increase was attributed principally to greater demand for blast-furnace coke, caused by a 8-million-ton increase in blast-furnace pig iron and ferroalloy production. Apparent consumption of coke in the United States in 1972, including a breakdown for that used in iron furnaces and for all other purposes, is shown in table 11.

The decline in blast-furnace coke consumption rates between 1968 and 1972 is shown in table 12. Except for slight increases in 1965 and 1970, the coke rate has declined each year during the past decade. The amount of coke required to produce 1 ton of pig iron and ferroalloys in blast furnaces in 1972 was only 1,222 pounds, compared with 1,351 pounds in 1963. The net effect of this 10% reduction in coke consumption rates over the 10-year period can best be emphasized by noting that if the 1972 output of 89.4 million tons of blast-furnace pig iron and ferroalloys had been produced in blast furnaces operating at the 1963 rate, total blast-furnace coke requirements for the year would have been 60 million tons, rather than the 55 million tons actually consumed.

Although a variety of operating practices affect blast-furnace coke rates, the pronounced reduction in the 1972 coke rate resulted mainly from a 67% increase in the quantities of fuel oil, tar, and pitch consumed over those used in 1971. The 289 million gallons of fuel oil and 64 million gallons of tar and pitch used as supplemental fuels in blast furnaces in 1972 were equivalent in calorific value to that contained in about 2 million tons of coke.

Tables 13 and 14 show the quantities of coke used and sold in each State in 1972. A total of 61 million tons of oven and beehive coke was sold and used for all purposes, of which about 90% was oven coke supplied by furnace plants. The bulk of this coke was retained by producers for use in their own blast furnaces. Furnace plants sold about 2 million tons of coke—25% of the total coke sold commercially. Approximately 50% of the furnace-plant sales was shipped to other blast-furnace plants.

Merchant plants distributed 5.4 million tons of coke in 1972, 97% of which was sold on the open market. Principal markets were blast-furnace operations without coke facilities, independent gray-iron foundries, nonferrous smelters, and chemical plants. A few merchant plants operate coke ovens to supply their own requirements; about 3% of the merchant coke distributed was used by producers. This coke was used principally in chemical plants and affiliated foundries.

One percent of the coke distributed was supplied by beehive plants. The bulk of the beehive coke also was sold to blast-furnace plants.

All States except Alaska, Hawaii, Nevada, and New Hampshire received shipments of coke in 1972. Alabama, Illinois, Indiana, Michigan, New York, Ohio, Pennsylvania, and West Virginia, which are the major iron- and steel-producing States, received about 85% of the total distributed.

The bulk of the coke distributed was blast-furnace coke that was consumed within the producing State, as most blast furnaces are integrated with coke ovens. A few companies shipped coke to affiliated blast furnaces in other States.

About 6% of the coke distributed was shipped to foundries. The chief recipients of foundry coke were the automotive, farm-machinery, machine-tool, heavy-machinery, railroad, and electrical-equipment industries. Most of these industries are concentrated in the East and Midwest. In 1972, the combined consumption of Alabama, Illinois, Indiana, Michigan, New Jersey, New York, Ohio, Pennsylvania, and Wisconsin accounted for about four-fifths of the foundry-coke shipments. Foundry coke also was consumed in 37 other States.

Coke used for miscellaneous applications was widely distributed, with 44 States receiving shipments of other industrial coke. The principal consumers were nonferrous smelters, alkali plants, and plants that manufacture calcium carbide and elemental phosphorus. Alabama, Idaho, Michigan, Ohio, and Pennsylvania received the largest quantities of other industrial coke.

Minor quantities of coke were used for residential heating. This market, which in past years received as much as 10 million tons of coke annually, is virtually nonexistent at this time.

STOCKS

Yearend stocks of coke decreased 16% as the quantity of coke distributed exceeded production by about ½ million tons. Oven-coke plants ended the year with an average 18-day supply at the December rate of production. Normally, beehive plants do not stock coke.

The bulk of the stock was at furnace plants, which had roughly a 17-day supply compared with a 23-day supply at merchant plants. There were no producers stocks of beehive coke at the end of 1972.

Stocks of coke breeze at producers' plants decreased 20% during 1972. Roughly, three-fourths of the breeze on hand was at furnace plants.

Data on stocks are shown in tables 16 and 17.

VALUE AND PRICE

Coke prices increased again during 1972; the average value of receipts for all grades of oven coke reached $40.70 per ton, and beehive coke averaged $22.04 per ton. The 1972 values represented increases of 9% for oven coke and 3% for beehive coke.

All grades of coke increased in price but "other industrial" and "residential heating" cokes, both of which increased about 25% in price, registered the largest percentage increases. Blast-furnace coke, which averaged $30.64 per ton, remained at virtually the same level as in 1971. Foundry coke, however, increased about 7%, to $51.16 per ton.

The large variance in the price of blast-furnace and foundry oven coke was attributed principally to lower recovery yields for foundry coke and to its superior properties, which make it a more valuable product. The differences in the average values of oven and beehive coke were due largely to additional transportation costs of coal delivered to oven-coke plants.

Average receipts, f.o.b. plant, for commercial sales of the different grades of coke, as reported by producers, are shown in table 18.

FOREIGN TRADE

There was a continuing demand for U.S. coke in foreign markets, but exports decreased 18% because of shortages of coke at home. Exports totaled 1.2 million tons, equivalent to about 2% of domestic output.

The principal foreign market was Canada which received 488,006 tons, about 40% of the foreign shipments. Other countries receiving substantial amounts of U.S. coke were West Germany, Mexico, the Netherlands, and Spain. Although coke was shipped to more than 21 countries in 1972, the above countries, with Canada, received nearly four-fifths of the total exports.

The bulk of the coke exported was shipped from the Baltimore, Buffalo, Cleveland, Detroit, Laredo, and Mobile customs districts. However, coke was exported through at least 18 other ports.

Table 19 shows exports of coke by country and customs district for 1970, 1971, and 1972. The total quantities shown for each year are substantially larger than those reported shipped by producers, as shown in table 15, because there were additional shipments to foreign countries by export companies.

Imports were insignificant, amounting to only 0.3% of apparent consumption. Ninety-three percent of the imported coke came from Canada, and almost all of the remainder was from the Republic of South Africa. Import data are shown in table 20.

COKING COALS

QUANTITY AND VALUE OF COAL CARBONIZED

A total of 87.3 million tons of bituminous coal was carbonized at high temperatures for the production of coke in 1972. This quantity was 15% of the 1972 bituminous coal output of the United States, and coke production was the second largest coal market. In addition to bituminous coal, 474,000 tons of anthracite was used in coking-coal blends. Anthracite was used principally in the production of foundry coke to achieve greater size and density, properties that are desirable in coke used for the smelting of iron in foundry cupolas.

The delivered average value of all coal carbonized by oven coke plants in 1972 was $15.73 per ton, and the value of that carbonized by beehive-coke plants averaged $9.85 per ton. The difference in value was attributed mainly to transportation charges for coal shipped to oven-coke plants, as all beehive plants are located at or near the source of the coal they consume. In some instances, transportation costs exceed the value of the coal at the mine; this partially accounts for the high value of the coal consumed in some States.

The average value per ton of coal consumed for coke production at both oven- and beehive-coke plants was about 13% greater than in 1971. Coals delivered to some States, however, had increases in average value per ton ranging up to 30%. The highest coal prices were recorded for Maryland and New York where the delivered value of coals used for coke production by all plants averaged $20.52 per ton.

An overall average of 1.45 tons of coal, valued at $22.81, was required for each ton of oven coke produced in 1972. Beehive ovens required an average of 1.62 tons of coal per ton of coke output, but coal costs averaged only $15.96 per ton because of the lower unit value of the coals charged.

Tables 22 to 25 present data on coals carbonized at oven- and beehive-coke plants.

BLENDING

Blending of coals is standard practice at oven-coke plants because individual coals do not possess all of the properties required for the production of high-quality coke. In general, blending is used to improve the chemical and physical properties of coke, to control the pressure developed during carbonization, to regulate the yield of products, and to broaden the use of lower-quality coals which could not be used alone for metallurgical-grade coke production. Standard oven-coke operating practice is based upon the use of relatively small proportions of low-volatile coals and high percentages of high-volatile coals. High-volatile coals are not used alone because they produce low yields and weak coke. Low-volatile coals, when added to high-volatile coals improve the yield and the physical properties of the coke. However, the proportions of low-volatile coals used must be restricted because they are highly expanding and, if used alone or in large proportions, would damage oven walls when coke was discharged. Some plants add medium-volatile coals or other materials such as anthracite or coal-tar pitch to their high- and low-volatile coals. Additions of medium-volatile coals can regulate the volatile matter in a mix to the desired content, while anthracite and pitch impart strength, size, and density to the coke.

Blending also permits the use of some high-sulfur coals which are otherwise unsuitable for coke production. Such coals can be blended with low-sulfur coals to the extent that the coal mix contains no more total sulfur than that contained in the coals normally used for producing high-quality coke.

The overall proportions of high-, medium-, and low-volatile coals used in coke mixes has varied little in the past decade, but there are wide variations in the proportions of the different types used by individual plants. West Virginia plants and those in the Western States used the largest percentages of high-volatile coals in their blends, while plants in Minnesota and Wisconsin used relatively high percentages of low-volatile coal. Compared with furnace plants, merchant plants used larger percentages of low-volatile coal because this type produces strong foundry coke, which is produced mainly by merchant plants.

Table 26 shows the quantities of coals carbonized at oven-coke plants, by volatile-matter content, for 1968–72. Table 27 shows the volatile-matter content of the coals received by oven-coke plants in various States.

SOURCES

Of the 23 States that produced bituminous coal in 1972, only 11 produced coking coal that was shipped to coke plants. Of this number, only 10 can be considered suppliers of coking coals as the combined shipments of Arkansas producers were only 115,000 tons.

Of the coals received by oven-coke plants, 35% was produced in West Virginia and 27% in Pennsylvania. West Virginia shipments were principally low-volatile coals from McDowell, Wyoming, and Raleigh Counties, medium-volatile coals from McDowell and Nicholas Counties, and high-volatile coals from Boone, Fayette, Kanawha, Logan, Marion, and Mingo Counties. Pennsylvania supplied mainly high-volatile coals from Green and Washington Counties and low-volatile coals from Cambria and Somerset Counties. Pennsylvania and West Virginia coals were widely distributed and used in most of the coke producing States.

Kentucky, which supplied 15% of the shipments to coke plants, was another major supplier. All Kentucky coal shipped to coke plants was high-volatile coal produced mainly in Floyd, Harlan, Letcher, and Pike Counties.

Illinois produced high-volatile coking coals, mainly in Franklin and Jefferson Counties; other States with substantial production were Alabama, Colorado, Utah and Virginia. Most of the coal produced in these States was used within the State. Colorado and Utah, however, supplied most of the coals that were carbonized in California.

Data showing the origin of coals received by oven-coke plants, by volatile-matter content, are shown in table 28, while table 29 shows the source of coals received by oven-coke plants in various States.

CAPTIVE COAL

More than one-half of the coal received by oven-coke plants was produced by company-owned or affiliated mines. This captive coal, ordinarily, does not move in commercial channels. Iron and steel producing companies own the bulk of the captive mines and, in 1972, 57% of the coal received by furnace plants was captive. Some merchant plants also own coal mines, but on 30% of the coal they received in 1972 was their own production.

The quantities of captive coal received by oven-coke plants in 1972 are shown in table 30.

STOCKS

Stocks of bituminous coal at oven-coke plants remained fairly constant throughout the year, ranging from an average supply of 35 to 43 days at each plant. Bituminous stocks reached their highest yearly level during June when month-end quantities totaled 10.1 million tons. The lowest level, 7.9 million tons, was reported at the end of January shortly after a curtailment in bituminous coal production because of a labor strike.

Bituminous stocks at the end of 1972 were 25% higher than when the year began. The 9 million tons on hand at all plants on December 31, 1972, was equivalent to an average supply on hand of 37 days at each plant, at the December rate of consumption.

Only small quantities of anthracite are stocked. Stocks at the end of 1972 totaled only 84,000 tons, 29% less anthracite than was on hand at the end of 1971.

COAL CHEMICALS

The term "coal chemicals" refers to the materials recovered from the volatile matter released from coal during carbonization. Normally, three basic materials—ammonia, tar, and light oil—are recovered at oven-coke plants through a series of complex condensation and absorption processes. The remaining material, which is rich in hydrogen and methane, is called coke-oven gas. Except for ammonia, which is recovered as an aqueous solution or converted to a salt and sold as produced, the basic materials are, in most instances, further processed to yield a number of primary organic chemicals or chemical mixtures of which the most important are benzene, toluene, xylene, solvent naphtha, crude chemical oil, and pitch. Although most oven-coke plants in the United States are equipped to process tar and light oil, the extent to which individual plants produce the various products depends upon economic conditions and the general size of the plant, as yields of the various chemicals are relatively low.

Yields of chemicals vary with the kind of coals carbonized, carbonizing temperatures, and operating techniques and equipment, but approximately 315 pounds of coke-oven gas, 90 pounds of tar, 20 pounds of light oil, and 5 pounds of ammonia are recovered for each ton of coal carbonized. In standard units of measure these quantities amount to about 10,500 cubic feet of coke-oven gas, 10 gallons of tar, and 3 gallons of light oil. Ammonia is recovered as ammonium sulfate at most operations, and the yield per ton of coal is approximately 18 pounds. Data on production and sales of basic chemical materials and derivatives at oven-coke plants in 1972 are shown in table 33.

Table 34 shows the heating value and coal equivalent of products other than coke produced at oven-coke plants. Although the quantities vary from year to year, most of the changes were due to differences in the amount of coal carbonized rather than fluctuations in yields. In terms of heating value, the products, not including coke, recovered in 1972 were roughly equivalent to the heating value of about one-fourth of the coal carbonized in slot ovens. Table 35 shows average values for the chemicals and surplus gas used and sold, compared with the unit values of the coke and breeze produced, from each ton of coal carbonized.

COKE-OVEN GAS

Coke-oven gas has a relatively high calorific value and producers use most of it as fuel for heating coke ovens and other steel- and allied-plant furnaces. Small quantities are also sold for distribution through city mains and for other industrial use.

Gas yields vary but the quantity of gas produced for each ton of coal carbonized in all slot ovens in 1972 was 10,570 cubic feet. This was slightly more than the yield of 10,510 cubic feet recorded for 1971. However, total gas production increased 6% because about 5 million more tons of coal was carbonized in 1972.

Table 37 shows coke-oven gas production by State, the quantities of gas used for heating ovens, and the amount of surplus gas used or sold. Of the total output, 40% was used at plants to heat coke ovens. Gas used otherwise, called surplus gas, is used by producers to fire boilers, transferred to steel or allied plants to heat open-hearth and other metallurgical furnaces, sold for industrial use, or distributed through city mains. A small part of the production was wasted because storage facilities at most plants are limited, and the gas was burned in the atmosphere when production exceeded demand.

Table 38 shows the disposal of surplus gas by the two segments of the oven-coke industry. Whereas about 90% of the surplus gas produced by furnace plants was consumed by producing companies, merchant plants used less than one-half of the surplus gas they produced. The largest portion of the merchant plant surplus was sold for industrial use.

Table 39 shows the quantities of various gases used to heat ovens in each State and the total gas consumption in terms of coke-oven gas equivalent. Coke-oven gas was the principal fuel used for heating slot ovens, but some operators used blast-furnace gas, a mixture of coke-oven and blast-furnace gas, or natural gas for underfiring. Nearly 400 billion cubic feet of coke-oven gas equivalent was so consumed, of which 91% was coke-oven gas, 8% was blast-furnace gas, and the remainder was natural gas.

Surplus coke-oven gas used and sold in 1972 was valued at $144 million, a 7% increase above the 1971 value. No value is reported by producers for coke-oven gas used to heat coke ovens, but applying the average value of $0.27 per thousand cubic feet reported for surplus gas to the gas used for underfiring, the total value of all coke-oven gas used and sold in 1972 would be $241 million. This amount is equivalent to nearly one-fifth of the total value of the coal carbonized at oven-coke plants.

COKE-OVEN AMMONIA

Coal carbonized at high temperatures releases nitrogen which forms ammonia. This ammonia must be removed from the gas prior to processing and coke plant operators normally recover ammonia as an aqueous solution or as ammonium sulfate or phosphate. However, because of increasing recovery costs and the relatively low value of the products recovered, some plants remove ammonia from the gas stream but do not recover it as a salable product.

Table 40 shows production and sales of ammonia products and yields in 1972 in terms of sulfate equivalent. Although one less plant recovered ammonia in 1972, production was about 4% greater than in 1971, principally because of higher recoveries.

Demand for coke-oven ammonia products declined in 1972 and sales of ammonium sulfate decreased 23% and ammonia liquor sales decreased 19%. The average value per ton, f.o.b. plant, of ammonium sulfate sold, however, increased $3.93 per ton, to $16.12. The total value of all ammonia products sold was $12.3 million, equivalent to 5% of the total value of all coal-chemical materials sold.

COAL TAR AND DERIVATIVES

All oven-coke plants produce tar. However, yields of tar vary widely among plants; in 1972, yields ranged from about 6.6 to 10.7 gallons per ton of coal carbonized. Generally, from 4 to 5% of the weight of the coals carbonized is recovered as tar. High-volatile coals evolve a larger percentage of tar; hence, California, Colorado, Indiana, Ohio, Utah, Pennsylvania and West Virginia, which used the most high-volatile coal in their blends, had the highest tar yields. Conversely, plants using higher percentages of low- and medium-volatile coals and anthracite, such as those mainly producing foundry coke, had the lowest yields.

Production of coal tar at oven-coke plants increased 10% in 1972. The average yield of tar increased slightly to 8.62 gallons per ton of coal, compared with 8.29 gallons in 1971. Table 41 shows the quantities of tar produced, used by producers, sold, and in stock in the various States at the end of 1972.

Coke-plant operators consumed 53% of the tar produced in 1972. Of this quantity, 69% was processed (refined or "topped"), 30% underwent no processing and was burned for fuel, and 1% was used for miscellaneous purposes, such as lining ingot molds, and for road materials and tar paints. The remaining 47% of the production was sold, principally to tar-distilling plants which refined the tar to produce a variety of derivatives.

Most of the coke plants that processed tar in 1972 "topped" tar. In so doing, the low-boiling distillate fraction, consisting mainly of tar acids, bases, and naphthalenes, was separated from the crude tar. The residue, called soft pitch, was, in most instances, burned for fuel. Furnace plants in particular benefit from this method of operation since they can sell the distillate and retain the pitch for use as fuel. This reduces the amount of other fuels that normally they must purchase. However, the relative quantities of tar topped and burned, as well as the quantities sold, depend upon a number of economic factors, such as the availability and current market prices of tar, tar distillates, and other substitute fuels. Most of the merchant plant tar production was sold because these plants have no use for the pitch, which makes up the bulk of the products they recover through topping.

The majority of the plants that processed tar in 1972 recovered only crude chemical oil and a residual tar, or soft pitch. However, some of the larger plants recovered a number of tar derivatives, including creosote oil, cresylic acid, cresols, naphthalene, phenol, pyridine, and medium and hard pitch. Statistics on some of these products could not be shown in this report, but the data were transmitted to the U.S. Tariff Commission, which publishes them along with similar data from tar distillers and petroleum refiners in monthly and annual reports on synthetic organic chemicals.

CRUDE LIGHT OIL AND DERIVATIVES

Light oil is a liquid that contains a number of aromatic hydrocarbons that are extracted from the gas after tar, ammonia, and in some instances, naphthalene have been removed. Crude tar also contains a small amount of light oil, but this usually is not recovered at coke plants. Virtually all light oil produced at coke plants is recovered by an absorption process in which the gas is sprayed with a higher boiling petroleum oil as the gas stream is channeled through absorption towers. After light oil is recovered, it is separated from the absorption oil by direct steam distillation. Approximately 3 gallons of light oil, equal to about 1% of the weight of the coal, is recovered for each ton of coal carbonized. Yields vary with the kind of coals carbonized and with operating conditions but an average of 2.66 gallons of light oil was recovered at plants that extracted light oil in 1972. Most plants recovered light oil, but some found it uneconomical to remove the light oil and left it in the gas to be burned as fuel. Yields per ton of coal increased at both merchant and furnace plants in 1972.

Producers sold 41% of their crude light oil output in 1972. The large increase in light oil sales in recent years is attributed principally to the inability of some plants to produce derivatives that meet the more rigid specifications established for these products. Such plants sell light oil to petroleum-refining companies which process it along with petroleum fractions into benzene, toluene, and a number of other chemical intermediates. Data on light oil and total derived products produced and sold in the various States are shown in table 42.

As with other coal-chemical materials, yields of products derived from light oil vary, but approximately 85% of the light oil processed is recovered as salable products. Yields of the various derivatives recovered through refining during 1972 and for prior years are shown in table 43.

Table 44 shows the quantities of the various grades of benzene and toluene produced at coke plants, while table 45 shows the principal light-oil derivatives produced and sold and yields of the various products by State. About 95% of the benzene is specification grade. In past years, large amounts of motor-grade benzene were produced for use in gasolines to increase antiknock properties, but present petroleum-refining techniques have all but eliminated this use for benzene. Production of all light oil derivatives was greater than in 1971, principally because a larger amount of light oil was refined.

WORLD REVIEW

World production of metallurgical coke in 1972 was estimated at 375 million short tons. This quantity was slightly higher than the 1971 output and the increase was attributed largely to small production gains in Poland, the United States, and the U.S.S.R.

Europe, with 58% of the total, led in world production. European output was about 1% less than in 1971, mainly, because of a substantial decrease in West German production. Asia, with seven producing countries, ranked second in output while North America, with only three producing countries, ranked third.

The Soviet Union, with nearly one-fourth of the world output, was the largest producer of coke. Soviet production increased 2% over that of 1971 and the estimated 88 million tons of coke and breeze produced in 1972 was a record output for the country. Metallurgical coke production, however, probably totaled about 84 million tons as an estimated 4 million tons of the production was breeze.

The United States, with 16% of the world total, ranked second in production, and Japan, with 11%, ranked third. The United States had a 5% production increase, but Japan's output was 1% below the level recorded in 1971.

Other leading coke-producing countries in order of output were West Germany, the People's Republic of China, the United Kingdom, and Poland. Although metallurgical-grade coke was produced in 32 other countries, the production of these countries combined with that of the U.S.S.R., the United States, and Japan accounted for more than three-quarters of the world production.

In addition to the metallurgical-grade coke, which is produced at high-temperatures in conventional slot- and beehive-coke ovens, there was 11 million tons of other coke that was produced at high, medium, and low temperatures in vertical and horizontal retorts and other types of carbonizing equipment. Commonly referred to as "gashouse" or "soft" coke, this material is not suitable for most metallurgical applications but is used principally for domestic heating, chemical processing, and gas production. Production of "gashouse" coke has been declining in recent years and the 1972 world output was only about one-fourth as large as a decade ago.

TECHNOLOGY

Studies[2] performed by the British Coke Research Association indicate that a reasonable estimate of the mean size of coke may be obtained from a singular linear dimension characteristic of the size of coke particles and its relationship to the mean size of the coke. Size is an important physical property of coke that determines, partially, the extent that certain cokes may be used effectively in particular applications. The size distribution of a sample of coke is assessed traditionally by a method, either mechanical or manual, which separates the coke by screening into discrete groups of pieces of similar size range. In this work, an expression was derived that made it possible to calculate the mean size of coke from the weight of a known number of coke particles. The expression was shown to be valid for coke within the overall size range of 20 to 160 millimeters and varying in apparent relative density from 0.84 to 1.03.

A laboratory investigation,[3] also by the British Coke Research Association, showed that both the quantity and particle size of breeze additions to coking coal charges influenced coke reactivity. Specifically, these studies showed that a coal charge containing up to 10% fine breeze (particle size of less than 38 micromillimeters) produced more reactive coke than the charge without breeze and that the reactivity for coke from a charge containing similar proportions of coarse breeze (particle size of from 1,200 to 210 micromillimeters) was less than for the charge with additions of fine breeze. Coke reactivity for charges of more than 10% breeze appeared to be modified; however, the breeze additions resulted in changes in coke porosity and these effects were more pronounced for breeze additions of particle size greater than about 120 micromillimeters.

A recent Bureau of Mines study[4] has found that cokes obtained from carbonization of certain high-volatile coals, when blended with fluidized-bed char and coke breeze, were significantly larger and stronger than cokes made from the same coals without such additions. In numerous bench-scale and other laboratory tests using Illinois No. 6 and a Kentucky High Splint coal, it was demonstrated that coke strength was improved most with a 12% addition of char and coke breeze in equal proportions and that such addition to the base coals was just as effective in improving the strength of coke produced as a 40% addition of high-quality low-volatile coal. Introduction of a proportion of low-volatile coal to the char-breeze Illinois coal blend improved the coke strength even further, although a similar addition to the High Splint blend did not result in as great an improvement in coke strength. The results of these experiments suggest that the use of premium low-volatile coking coals in certain metallurgical coking-coal mixes could be eliminated by additions of char and coke breeze.

Developmental work at coke plants continued to be focused upon systems for reducing atmospheric pollution. A number of systems and practices, including pipeline charging, the use of door machine hoods, and a smokeless charging system, developed through supporting research by the American Iron and Steel Institute, the Environmental Protection Agency, and several steel companies, have been installed at a number of plants. All, however, are experimental in nature and air-pollution control continues as the major operating problem of coke plants.

Relief from the pollution problems associated with coke quenching might possibly be obtained through the use of a Soviet process[5] for dry-quenching, which was described and demonstrated recently at a Symposium on Soviet Anti-Pollution Technology. This process features a completely closed system that, it was claimed, quenches coke without pollution, produces coke with improved properties, increases pig iron output per ton of coke and conserves energy by steam generation within the system. It was claimed, also, that this process has effectively eliminated quenching pollution problems at 28 Soviet coke-oven batteries that have been fitted with the system and the system has been so successful that 19 more dry-quenching units are under construction in the U.S.S.R.

A $25 million experimental plant that will produce 500 tons of form coke per day is now under construction at Sparrows Point, Md. A joint venture of the Bethlehem, National, and Republic Steel Corporations and Consolidation Coal Company, the plant, reportedly, will produce form coke suitable for blast furnace use by hot-pelletizing fine coal, after which the product is calcined. The system, which is fully enclosed, will minimize the problems of air and water pollution now experienced in conventional coke making.

A system for disposing of waste liquids from coke plant operations has been installed at the Alan Wood Steel Company coke plant at Swedeland, Pa. With this process, waste liquid is passed through successive stages of distillation and evaporation, yielding vapors and a concentrated solution of dissolved solids. The vapors and dissolved solids are incinerated; the distillate is purified by activated carbon, producing clean water.

[1] Calculated by dividing production by coal carbonized at plants actually recovering breeze.

[2] Included with "Undistributed" to avoid disclosing individual company confidential data.

[3] Data may not add to totals shown because of independent rounding.

Table 10.—Oven- and beehive-coke breeze used and sold in the United States, by use

(Thousand short tons)

Year	Used by producers: In steam plants	Used by producers: In agglomerating plants	Used by producers: For other industrial use	Sold	Average value per ton
1968	508	1,634	589	1,364	7.34
1969	439	1,650	775	1,538	8.13
1970	366	1,948	704	[1] 2,067	9.74
1971	309	1,582	650	1,879	10.80
1972	265	1,305	704	[1] 2,113	10.59

[1] Does not include beehive-coke breeze sold (to avoid disclosing individual company data).

Table 11.—Apparent consumption of coke in the United States

(Thousand short tons)

Year	Total production	Imports	Exports	Net change in stocks	Apparent consumption [1]	Consumption: In iron furnaces [2]: Quantity	Consumption: In iron furnaces [2]: %	Consumption: All other purposes: Quantity	Consumption: All other purposes: %
1968	63,653	94	792	+517	62,438	56,238	90.1	6,200	9.9
1969	64,757	173	1,629	−2,865	66,166	60,176	90.9	5,990	9.1
1970	66,525	153	2,478	+993	63,207	58,151	92.0	5,056	8.0
1971	57,436	174	1,509	r −588	r 56,689	51,498	90.8	5,206	9.2
1972	60,507	185	1,232	−586	60,029	54,607	91.0	5,422	9.0

r Revised.

[1] Production plus imports minus exports, plus or minus net change in stocks.

[2] American Iron and Steel Institute; figures include coke consumed in manufacturing ferroalloys.

Table 12.—Coke and coking coal consumed per short ton of pig iron and ferroalloys produced in the United States

Year	Coke per short ton of pig iron and ferroalloys [1] (pounds)	Yield of coke from coal (%)	Coking coal per short ton of pig iron and ferroalloys (pounds, calculated)
1968	1,263.4	69.8	1,810.0
1969	1,260.4	69.4	1,816.1
1970	1,266.6	69.1	1,833.0
1971	1,260.8	69.0	1,827.2
1972	1,221.6	69.1	1,771.5

[1] American Iron and Steel Institute; consumption of coke per ton of pig iron only, excluding furnaces making ferroalloys, was 1,248 in 1968; 1,252 in 1969; 1,260 in 1970; 1,254 in 1971; and 1,216.2 in 1972.

Table 13.—Oven coke produced in the United States, used by producers, and sold in 1972, by State

Grand total	[r] 414,723	397,667	397,520

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed, Algeria, Arab Republic of Egypt, Malaysia, People's Republic of China, Mexico, Norway, Romania and the U.S.S.R. have produced gashouse coke in previous years and may have continued production into the time period covered by this table, but no statistics are available and information is inadequate to make reliable estimates of output levels. Japan also produces low temperature coke but data are not available except where otherwise noted, coke breeze has been excluded from this table.

[2] Coke produced at high temperature in conventional carbonizing equipment (including slot and beehive coke ovens).

[3] Includes beeeze.

[4] Includes relatively small amounts of gas coke.

[5] Includes relatively small amounts of low-temperature coke.

[6] Data are total of so-called hard coke production from collieries and coke plants (including those at steelworks).

[7] Data are for years beginning March 21 of that stated.

[8] Includes coke produced at high temperatures in carbonizing equipment designed primarily for gas manufacture. (Horizontal and vertical coal-gas retorts.) In addition to countries listed, Canada and Finland produce gas coke but output is not reported separately from metallurgical coke and the output has been included in that section of this table.

[9] Data are for years beginning March 31 of that stated.

[10] Includes coke produced at low and medium temperatures, as well as produced in unconventional equipment (chain-grate cokers).

[11] Includes coke produced from lignite at high temperatures.

Table 22.—Quantity and value at ovens of coal carbonized in the United States in 1972, by State

State	Coal carbonized			Coal per ton of coke

Table 33.—Coal-chemical materials, exclusive of breeze, produced at oven-coke plants in the United States in 1972 [1]

Product	Produced	Sold			On hand Dec. 31
		Quantity (thousands)	Value		
			Total (thousands)	Average per unit	
Tar, crude ... thousand gallons	747,186	340,875	$39,634	$0.116	51,436
Tar derivatives:					
Sodium phenolate or carbolate ... do	3,007	2,837	211	.074	178
Crude chemical oil (tar acid oil) ... do	9,731	9,722	1,469	.151	122
Pitch of tar: [2]					
Soft ... thousand short tons	326	137	5,149	37.584	7
Hard ... do	209	97	4,109	42.361	4
Other tar derivatives [3]	--	--	12,469	--	--
Ammonia products:					
Sulfate ... thousand short tons	564	471	7,588	16.110	83
Liquor (NH_3 content) ... do	13	13	614	47.231	2
Diammonium phosphate ... do	41	39	4,120	105.641	2
Total ... do	--	--	12,322	--	--
Sulfate equivalent of all forms ... do	656	559	--	--	92
NH_3 equivalent of all forms ... do	169	144	--	--	24
Gas:					
Used under boilers, etc ... million cubic feet	--	102,360	27,241	.266	--
Used in steel or allied plants ... do	--	364,896	101,307	.278	--
Distributed through city mains ... do	[4] 916,011	11,392	3,947	.347	--
Sold for industrial use ... do	--	55,843	11,397	.204	--
Total ... do	[4] 916,011	534,491	[5] 143,893	.269	--
Crude light oil ... thousand gallons	[6] 214,201	86,915	9,584	.110	10,151
Light oil derivatives:					
Benzene:					
Specification grades (1°, 2°, 90%) ... do	76,317	76,739	15,847	.207	2,507
Other industrial grades ... do	3,532	3,486	491	.141	67
Toluene (all grades) ... do	14,571	13,954	2,501	.179	810
Xylene (all grades) ... do	3,351	3,208	578	.180	517
Solvent naphtha (all grades) ... do	2,815	2,596	462	.178	242
Other light oil derivatives ... do	3,898	2,520	849	.337	335
Total ... do	104,484	102,503	20,728	.202	4,478
Intermediate light oil ... do	3,704	754	70	.093	214
Grand total	--	--	[5] 249,638	--	--

---

[1] Includes products of tar distillation conducted by oven-coke operators under the same corporate names.

[2] Soft-water-softening point—less than 110° F; medium—110° to 160° F; hard-oven—160° F. Figures on hard pitch includes small amount of medium pitch.

[3] Creosote oil, cresols, cresylic acid, naphthalene, phenol, pyridine, refined tar, tar paint.

[4] Includes gas used for heating ovens and gas wasted.

[5] Data may not add to total shown because of independent rounding.

[6] 119,485,000 gallons refined by coke-oven operators to make derived products shown.

Table 34.—Coal equivalent of the thermal materials, except coke, produced at oven-coke plants in the United States

Year	Materials produced				Estimated equivalent in heating value [1] (billion Btu)					Coal equivalent (thousand short tons)
	Coke breeze (thousand short tons)	Surplus gas (billion cubic feet)	Tar (thousand gallons)	Light oil (thousand gallons)	Coke breeze	Surplus gas	Tar	Light oil	Total	
1968	4,074	575	760,812	238,887	81,480	316,250	114,114	31,055	542,899	20,721
1969	4,401	595	768,766	258,910	88,020	327,250	115,315	33,658	564,248	21,536
1970	4,665	585	760,926	244,107	93,300	321,750	114,139	31,734	560,923	[r] 21,409
1971	4,048	507	679,377	201,626	80,960	278,850	101,907	26,211	487,928	18,623
1972	4,261	534	747,186	214,201	85,220	293,700	112,078	27,846	518,844	19,740

[1] Breeze, 10,000 Btu per pound; gas, 550 Btu per cubic foot; tar, 150,000 Btu per gallon; and light oil, 130,000 Btu per gallon.

Table 35.—Average value of coal-chemical materials used or sold and of coke and breeze per short ton of coal carbonized in the United States

	1968	1969	1970	1971	1972
Ammonia products	$0.194	$0.173	$0.151	$0.136	$0.142
Light oil and its derivatives	.427	.435	.405	.365	.350
Surplus gas used or sold	1.483	1.502	1.561	1.640	1.660
Tar and its derivatives (including naphthalene):					
Tar burned by producers [1]	.311	.317	.398	.341	.366
Sold	.727	.685	.623	.721	.727
Total	3.142	3.112	3.138	3.203	3.245
Coke produced	12.246	[2] 12.560	[2] 19.208	[2] 21.135	[2] 22.978
Breeze produced	.314	.388	.481	.534	.533
Grand total	15.702	16.060	22.827	24.872	26.754

[1] Includes pitch-of-tar.

[2] Average value of coke used or sold.

Table 36.—Percentage of coal costs recovered from the recovery of coal-chemical materials in the United States

	1968	1969	1970	1971	1972
Product:					
Ammonia products	1.9	1.8	1.3	1.1	1.0
Light oil and its derivatives	4.3	4.4	4.3	3.8	3.2
Surplus gas used or sold	15.1	14.4	12.8	11.7	10.6
Tar and its derivatives used or sold (including naphthalene)	10.4	10.5	9.0	8.0	8.0
Total	31.7	31.1	27.4	24.6	22.8
Value of coal per short ton	$10.01	$10.42	$12.21	$14.00	$15.74

Table 37.—Production and disposal of coke-oven gas in the United States in 1972, by State

(Million cubic feet)

State	Produced		Used in heating ovens	Surplus used or sold			Wasted
					Value		
	Total	Thousand cubic feet per ton of coal		Quantity	Thousands	Average per thousand cubic feet

[1] Number of plants that recovered ammonia.
[2] Includes diammonium phosphate.
[3] Included with "Undistributed" to avoid disclosing individual company data.
[4] Data may not add to totals shown because of independent rounding.
[5] Comprises 564,000 tons of ammonium sulfate and 41,000 tons of diammonium phosphate.
[6] Included with furnace plants to avoid disclosing individual company data.
[7] Included with merchant plants to avoid disclosing individual company data.
[8] Comprises 471,000 tons of ammonium sulfate valued at $7,588,000 and 39,000 tons of diammonium phosphate valued at $4,120,000.

Columbium and Tantalum

By Joseph A. Sutton [1]

The 1972 demand for columbium and tantalum in steelmaking continued an upward trend that began in 1968. For steelmaking purposes consumption of ferrocolumbium (FeCb), ferrotantalum-columbium (FeTa–Cb), and other columbium and tantalum materials totaled 2.9 million pounds in 1972. The primary use of these materials was for the production of high strength-low alloy steels. During the year while imports of columbium mineral concentrates and the price of columbium raw materials in the forms of columbite and pyrochlore concentrates were increasing, approximately 2.3 million pounds of combined pentoxides were awarded to industry from Government stocks. The primary use of tantalum continued to be for capacitors in the electronics industry. The chemical industry for the first time used large sheets of thin-gage tantalum to make pressure vessels that were to be used in the Kel-Chlor process for recovering chlorine from byproduct hydrogen chloride.

Legislation and Government Programs.—During 1972 the Office of Minerals Exploration (OME), U.S. Geological Survey, continued to offer financial assistance of 50% (columbium) and 75% (tantalum) of costs for exploration of approved columbium and tantalum resources.

The General Services Administration (GSA) continued its columbium disposal program and sold to industry 1,857,382 pounds of columbium and 380,209 pounds

of tantalum in the forms of columbium ores and concentrates, 282,370 pounds of columbium in the form of ferrocolumbium and 14,289 pounds of columbium in the form of columbium oxide powder. Of the quantities of columbium and tantalum awarded in the forms of columbium ores and concentrates, 498,366 pounds of columbium and 70,348 pounds of tantalum were sold on a negotiated bid basis at a value of $708,833 in payment for other commodities furnished to GSA. The value of all sales of columbium-bearing materials in 1972 was $4,076,054. The quantities of columbium and tantalum materials reported in Government inventories as of December 31, 1972, are listed on table 3.

DOMESTIC PRODUCTION

Domestic mining activity was insignificant during the year. One company produced a few pounds of columbium and tantalum while doing exploration and development work in Larimer County, Colo., but none of the material was marketed.

Production of columbium metal powder decreased 43% in 1972, but data continued to be withheld to avoid disclosing individual company confidential data. Production of columbium metal ingot decreased 64%, but again specific information was withheld. Production of tantalum metal powder (including capacitor-grade powder) increased 51% to 676 tons in 1972; production of tantalum metal ingot increased 52% to 257 tons.

Ferrocolumbium and columbium master alloys were produced by the thermite process by the Reading Alloys, Co., Inc., and Shieldalloy Corp. Foote Mineral Co., Kawecki Division of Kawecki Berylco Industries, Inc., and Union Carbide Corp. produced the material in electric furnaces. During the last 3 years no production of ferrotantalum-columbium has been reported by the industry.

CONSUMPTION AND USES

Consumption of columbium in the form of high-purity metal totaled 217,562 pounds, a decrease of 47% from the total for 1971. Tantalum metal (including capacitor-grade powder) consumed during the year increased 42% and totaled 921,851 pounds. Tantalum metal continued to be used primarily in powder or ingot form in the manufacture of capacitors, other electronic equipment, and corrosion-resistant chemical equipment.

Consumption of ferrocolumbium (FeCb), ferrotantalum-columbium (FeTa–Cb), and other columbium and tantalum materials increased in all end-use categories except carbon steels. The largest single-volume increase occurred in high strength-low alloy steels. Total consumption of columbium plus tantalum increased 28% to nearly 3.7 million pounds in 1972. Domestic consumption of FeCb, FeTa–Cb, and other columbium and tantalum materials, by major end-use categories, was as follows: High strength-low alloy steel (31%), carbon steel (20%), superalloys (18%), stainless and heat-resisting steel (18%), full alloy steel (8%), miscellaneous and unspecified (4%), and alloys other than alloy steels and superalloys (1%).

The total quantity of ferrocolumbium consumed in steelmaking (excluding electric and tool steels) was approximately 2.8 million pounds, an increase of 28% over the total for 1971. Consumption of ferrotantalum-columbium continued to be small and amounted to less than 1% of the FeCb, FeTa–Cb, and other columbium and tantalum materials consumed. Stainless and heat-resisting steel continued to be the major end-use categories for FeTa–Cb.

Consumption of other tantalum and columbium materials was about 5% of the total FeCb, FeTa–Cb, and other columbium and tantalum materials consumed. Superalloys remained as the major end-use category for other tantalum and columbium materials.

American Metal Climax Inc. acquired the assets of the former General Electric Refractory Metals Center in Cleveland, Ohio. The 85,000-square-foot facility contains a variety of plate, sheet, strip, and foil rolling equipment for mill products of molybdenum, tungsten, zirconium, columbium, and tantalum, as well as superalloys.[2]

Fansteel Inc. phased out its tantalum rolling operations in Baltimore, Md., and moved them to its North Chicago, Ill., plant in an effort to improve efficiency.

The Metals Division of the Norton Co., a producer of tantalum powders and mill products, made plans to market tantalum carbide powders.[3]

IN–657, a new nickel alloy, was developed in the Birmingham research laboratory of International Nickel Co. The new nickel alloy, containing 50% chromium and 1.5% columbium, combines great strength and resistance to corrosion at high temperatures. The recent development of large sheets of thin-gage tantalum coupled with new welding techniques and explosion-bonding methods of cladding have made it possible for the chemical industry to use tantalum in large pressure vessels. Such vessels are to be used in the M. W. Kellogg Kel-Chlor process to recover chlorine from byproduct hydrogen chloride.[4]

Nickel-copper-columbium alloy steels, developed by the International Nickel Co., provided new avenues of approach in the design and fabrication of complex high structures.[5] One unique example of this occurred in the construction of mobile cranes. The use of these low-carbon nickel-containing ferritic steels made it possible to design a relatively lightweight unit that provides excellent long-reach performance for the telescopic boom section of the crane.

Single and double sling chain made entirely from Carpenter No. 20 Cb–3 stainless steel was reported to have a longer service life in sulfuric acid pickling operations than chains made from the 300 series stainless steels.[6]

STOCKS

The following yearend columbium and tantalum materials (given in pounds) were reported in inventories:

Material	Dec. 31, 1971	Dec. 31, 1972
COLUMBIUM		
Primary metal	60,303	55,984
Ingot	45,324	62,826
Scrap	67,503	75,483
Oxide	1,051,357	553,800
Other compounds	[r]527,976	142,539
TANTALUM		
Primary metal	269,249	267,975
Capacitor-grade powder	163,320	154,871
Ingot	86,452	56,074
Scrap	[r]272,359	232,039
Oxide	[r]106,700	90,386
Potassium tantalum fluoride (K_2TaF_7)	[r]246,760	163,606
Other compounds	53,536	12,802

[r] Revised.

Stocks of columbium and tantalum raw materials, as reported by consumers and dealers at yearend 1972, were as follows (in short tons—1971 figures in parentheses): Columbite, 1,104 (521); tantalite, 1,120 (1,322); pyrochlore, 501 (595); tin slag, 33,775 (35,787); and other, 61 (none).

Consumers inventories of ferrocolumbium and ferrotantalum-columbium as of December 31, 1972, were as follows (with 1971 yearend stocks in parentheses): Ferrocolumbium, 814,607 pounds contained columbium (758,828); ferrotantalum-columbium, 18,592 pounds contained columbium plus tantalum (34,737); and other columbium and tantalum materials, 40,061 pounds contained columbium plus tantalum (31,818). Producer stocks of ferrocolumbium at yearend 1972 were 638,000 pounds contained columbium (534,000).

PRICES

Prices for columbite and pyrochlore, as reported by Metals Week, were higher at the end of 1972 than at the end of 1971. Columbite ore, c.i.f. U.S. ports, increased from $0.75–$0.85 per pound of contained pentoxides for material having a Cb_2O_5-to-Ta_2O_5 ratio of 10 to 1 at the beginning of the year to $1.10–$1.15 per pound at yearend. Contract rates for Canadian pyrochlore, f.o.b. mine and mill, went from $1.15–$1.20 per pound of Cb_2O_5 content to $1.37 after being down to $0.95 in the first quarter. Those for Brazilian pyrochlore similarly went from $1.15 to $1.37. Spot prices for tantalite ore, 60-percent basis, c.i.f. U.S. ports, were quoted at $6.25–$6.75 per pound Ta_2O_5 at the beginning of the year and $5.25–$6.00 per pound at yearend.

Quoted prices for various grades of ferrocolumbium were unchanged during the year: Low-alloy standard grades, ton lots, f.o.b. shipping point, $2.45–$2.65 per pound of columbium content; high-purity grades, $4.12–$6.81.

The price of columbium and tantalum metal remained unchanged during the year. Columbium powder was quoted at

$11 to $22 per pound for metallurgical-grade material, and $12 to $23 per pound for reactor-grade material. Columbium ingot was quoted at $16 to $27 per pound for metallurgical-grade material, and $17.50 to $28.00 per pound for reactor-grade material. Tantalum metal was quoted at $38.50 to $47.00 per pound for powder, $36 to $60 per pound for sheet, and $36 to $50 per pound for rod.

Table 7.—Average grade of concentrate received by U.S. consumers and dealers in 1972, by country of origin

[2] Material reported from Brazil or Canada as columbite represents primarily pyrochlore.

FOREIGN TRADE

Most of the columbium and tantalum exported from the United States was received by West Germany, Japan, and the United Kingdom. Tantalum and tantalum alloy powder, the largest export item by quantity and value, was shipped to Japan (29%), West Germany (24%), the United Kingdom (19%), France (11%), Italy (6%), Austria (4%), and the Netherlands (3%). The remainder of the tantalum and tantalum alloy powder (4% of the total) was destined for Canada, Switzerland, Australia, India, Sweden, New Zealand, and Belgium-Luxembourg. Unwrought tantalum alloys in crude form and scrap, the second largest export item by volume, was destined for West Germany (55%), Japan (16%), the United Kingdom (11%), Italy (5%), Belgium-Luxembourg (4%), and Austria (4%). The remainder of this material (5% of the total) was exported to France, Canada, Mexico, Brazil, Norway, and the Netherlands. Wrought tantalum and tantalum alloys, the second largest export item by value, was shipped to the United Kingdom (23%), Japan (19%), France (17%), West Germany (16%), Switzerland (7%), Canada (5%), and Italy (4%). The remainder of the tantalum material (9% of the total) was exported to Austria, the Netherlands, Mexico, Belgium-Luxembourg, India, Argentina, Australia, Brazil, Sweden, Ireland, Israel, Gibraltar, and the Republic of South Africa. Tantalum ore and concentrate, believed not to be of domestic origin, was shipped to Japan (62%), the United Kingdom (29%), and West Germany (9%). Wrought columbium and columbium alloys were mostly exported to West Germany (55%), Japan (17%), the United Kingdom (9%), the Republic of South Africa (7%), Canada (6%), and France (5%). The rest of this columbium material (1% of the total) was exported to Belgium-Luxembourg, Italy, and Czechoslovakia. Unwrought columbium alloys in crude form and scrap were shipped mostly to West Germany (68%), Japan (16%), and Canada (11%); the remainder (5% of the total) went to Saudi Arabia and Switzerland.

Imports for consumption of unwrought columbium metal, waste, and scrap, all from West Germany, decreased from 450 pounds valued at $7,227 in 1971 to 400 pounds valued at $3,714 in 1972. In 1972 imports for consumption of wrought columbium metal increased to 265 pounds valued at $14,876 from 76 pounds valued at $16,526 in 1971. This import item came from Belgium-Luxembourg (84%), Canada (10%), the Netherlands (5%), and the United Kingdom (1%). Unwrought columbium alloys were not imported in 1972.

Imports for consumption of unwrought tantalum metal, including waste and scrap, increased approximately 80% in 1972 to 72,246 pounds valued at $543,109. Imports of wrought tantalum, from Australia (51%) and Canada (49%), decreased from 111 pounds valued at $5,214 in 1971 to 90 pounds valued at $3,664 in 1972. Imports of unwrought tantalum alloys, all from West Germany, totaled 2,000 pounds valued at $13,183 and represented a sharp increase over the 7 pounds valued at $279 that were imported in 1971.

WORLD REVIEW

Australia.—Vultan Minerals Ltd. initiated steps to mine a new area for tin and tantalite near its Queenbushes plant in West Australia. Preliminary tests have indicated the presence of sufficient ore to justify the erection of a simple treatment plant, the output from which is to be transported to the main plant for upgrading.[7]

Brazil.—During 1972 Brazil maintained its standing as the major producer of columbium minerals. Companhia Brasileira de Metalúrgia e Mineração (CBMM), the country's leading producer, continued to recover columbium from rich pyrochlore ores at the Araxá mine and to produce ferrocolumbium (FeCb) at its pyrometallurgical plant. Production of columbium oxide in 1972 was 58% above the 8,038,000 pounds produced during 1971. This increase was attributed largely to the increased consumption of columbium in pipeline and other high-strength, low-alloy steels. In 1971, approximately 3.2 million pounds of FeCb were produced from 5.3 million pounds of pyrochlore concentrate. With the exception of approximately 0.3 million pounds sold domestically and approximately 0.6 million pounds that apparently went into stocks, all of the FeCb was exported to the United States (1.2 million pounds), continental Europe (0.6 million pounds), Japan (0.3 million pounds), Canada (0.1 million pounds), and the United Kingdom (0.1 million pounds).

---

[7] Metal Bulletin (London). Vultan Extends Operations. No. 5684, Mar. 17, 1972, p. 15.

In 1972, an arrangement was consummated between CBMM and the state-owned Companhia Agricola de Minas Gerais (CAMIG) for the joint mining of pyrochlore from their respective mining concessions near Araxá, Minas Gerais, thus ending a lengthy dispute over mining on CAMIG ground by CBMM on a royalty payment basis. Under the new arrangement, which is to become effective on January 1, 1973, a new firm, Companhia Mineradora do Pirocloro de Araxá (COMPIRA), was formed. The new firm was to lease the mining concessions from CAMIG and CBMM, and was to sell pyrochlore ore on a cost plus 10% basis to CBMM exclusively for beneficiation to concentrate (± 60% Cb_2O_5) or the manufacture of ferrocolumbium. CBMM was to be the marketing agent for these products, and CAMIG was to participate in the net profits from the sale of columbium products. This new arrangement between CAMIG and CBMM was to continue for 30 years, with an automatic extension for another 30 years unless either party wishes to withdraw. Fifty-one percent of COMPIRA is to be owned by CAMIG and 49% by CBMM.

Columbium and tantalum in columbite-tantalite and microlite continued to be produced in limited quantity from relatively small pegmatite operations located principally in Minas Gerais. All output was exported. In 1970 these exports amounted to 90,389 pounds of columbite and 458,557 pounds of tantalite, the United States being the principal destination. In 1971 comparable exports were 138,890 pounds and 639,334 pounds, respectively, and the United States again was the principal destination.

Canada.—St. Lawrence Columbium and Metals Corp. produced concentrates from its underground mining operations and mill facilities near Oka, Quebec, and continued to be Canada's sole columbium producer. The operations in fiscal 1972 (ended Sept. 30, 1972) milled 589,147 tons of ore, an increase of 44% over the 408,500 tons produced in fiscal 1971.

About 70,000 feet of diamond drilling and metallurgical tests have established that the St. Honore carbonatite deposit, near Chicoutimi, Quebec, was one of the largest columbium deposits in the world.[8] It consists of two mineralized zones totaling 60 million tons of ore of about 0.66 percent Cb_2O_5. It was stated in the agreement between the two companies, Copperfields Mining Corp. Ltd. and the Quebec Government exploration company Quebec Mining Exploration Co. (SOQUEM), that, following various financing operations for each stage of development, each party would hold a working interest of 50%. It was expected that underground operations would start in 1973.

The geology of a major pyrochlore deposit located in the lowlands of Northern Ontario and known as the James Bay deposit was described in a recent article.[9]

Tantalum Mining Corporation of Canada, Ltd. (TANCC), a wholly owned subsidiary of Chemalloy Minerals Ltd., has found what appears to be a new tantalum ore body at its Bernic Lake, Manitoba, property. The new zone was located in a granite pegmatite sill which underlies and parallels the ore zone presently being mined. The first and second drill holes cut ore reading 0.19% and 0.24% Ta_2O_5, respectively.

Japan.—The Japanese company, Showa Denko, was waiting for approval from the Ministry of International Trade and Industry (MITI) on a proposal for a financial and technical link with Kawecki Berylco Industries, Inc., of the United States for the setting up of a tantalum-producing company that would allow full integration (refining to fabricating) of tantalum products. The proposal also involved transferring production of tantalum powder from the Showa Denko plant at Higashi Nagahara to the new company. This plant's current output of tantalum powder was reported to be 30 tons annually.[10]

MITI was considering a program for Japan Rare Metals Co. to set up stockpiles in Japan of minor metals and ores, such as tantalum, beryllium, columbium, zirconium, and rare earths, as a means of controlling demand and supply and thus of stabilizing prices.[11]

[9] Stockford, H. R. The James Bay Pyrochlore Deposit. Canadian Min. and Met. Bull., v. 65, No. 722, June 1972, pp. 61–69.

[10] World Minerals and Metals. Tantalum Project Proposed. No. 6, March/April 1972, p. 26.

The Japanese tantalum industry received many inquiries from Peking for tantalum powder and products and was anticipating a trade boom with the People's Republic of China.[12]

Nigeria.—The Quebec and Titanium Corp., a Canadian subsidiary of Kennecott Copper Corp., plans to sell its holdings in the Tin and Associated Mining, Ltd. (TAM) columbite mine. The completion of the sale was contingent upon the necessary investment guarantee by the Japanese Government to Mitsubishi Corp. and Sumitomo Metal Mining Co., Ltd., as well as on agreement from the Nigerian Government to the ownership transfer.

The Kennecott Copper Corp. considers TAM too small an operation to warrant the funds and effort required to establish the mine on an economically viable basis. Difficulty in recruiting satisfactory expatriate personnel to manage and operate the mine in its isolated location coupled with the general decrease of columbite prices has decreased Kennecott's interest in the mine.

Thailand.—Tantalum-bearing slags produced by Thailand Smelting and Refining Company, Ltd. (THAISARCO), a 50–50 venture between Union Carbide Corp. and Royal Dutch Shell, are to be sold by Billiton Trading Co., a subsidiary of Billiton Handelsgesellschaft.[13] Union Carbide, which has been responsible for the management and tantalum sales, was to retain its ownership in THAISARCO, but the Billiton Trading Co. was to assume the responsibility for worldwide marketing of the Thai slags containing 12% Ta_2O_5 and 7% Cb_2O_5. THAISARCO produces an estimated 600,000 pounds of Ta_2O_5 annually.

Zaire.—The greatest economic wealth of Zaire was reported to be in its minerals, which provide 80%, by value of the nation's exports and supply 45% of Government revenues. The high costs of in-country transportation have cut into the profit margins that were enjoyed by mining companies in the late 1960's. The squeeze has been felt more in Kivu Province where cassiterite, gold, wolframite, and columbium-tantalum ore are the basic products of the mines and where transportation is a bigger problem. Société Minière Union Carbide-Somikubi (SOMUCAR), a mining company in Kivu Province in which Union Carbide held a 50% interest, closed down after studies showed that the planned pyrochlore production would be uneconomic.

Zaire-Etain, a Zairian company owned 50% by the Government and 50% by the Compagnie Géologique et Minière des Ingénieurs et Industriels Belges (GÉOMINES), produced 143,299 pounds of columbium-tantalum as a byproduct of tin mining in 1971, which was approximately 35,000 pounds less than that produced in 1970. The company employs 49 Europeans and 114 Zairian management personnel and 2,700 workers.

Philips Brothers Sobaki (PHIBRAKI), owned 50% by Philips/Englehard (South African) and 50% by SOBAKI of the Empain group (Belgian), produced mixed cassiterite and columbium-tantalum ore from deposits at Kabili. Production in 1971 was 205,910 pounds, 24% above the 165,632 pounds produced in 1970. Cobelmin-Zaire, a Zairian subsidiary of Compagnie Belge d'Entreprises Minières (MGL), operates the concessions owned by MGL. Production of columbium-tantalum concentrates in 1971 was 108,828 pounds.

TECHNOLOGY

A report issued by the Bureau of Mines showed that columbium, tantalum, zirconium, and titanium can be separated from waste residues generated by the chlorination of rutile used for production of titanium tetrachloride ($TiCl_4$).[14]

Engineers at Argonne National Laboratory and the Institute for Experimental Particle Physics, Karlsruhe, West Germany, developed a technique for building particle accelerator components of superconducting columbium.[15] The Argonne National Laboratory reports that instability problems with columbium have been solved. Components of superconducting columbium when cooled to liquid helium temperatures can generate electric fields as high as 800,000 volts per foot, and require only 1/50,000 the power needed by similar devices of conventional copper construction.

Scientists at RCA Laboratories in Princeton used columbium-gallium to achieve superconductivity at a temperature above 20° K.[16]

Westinghouse Electric Corp. displayed a prototype electric generator with a magnet core refrigerated to minus 452.2° F.[17] The superconducting magnet, made by the winding of 2 miles of columbium-titanium alloy wire 1/1000 inch in diameter and cooled with helium, carries 50 times more electricity than conventional generator windings of that size, and produces a magnetic field three or four times greater.

The continuing interest in methods of upgrading and extracting tantalum and columbium values from tin slags was reflected by a patent issued during the year.[18]

^{e} Estimate. ^{p} Preliminary. ^{r} Revised.

[1] Data generally has been presented as reported in sources, divided into columbite concentrate and tantalite concentrate where information is available to do so, reported as columbite-tantalite where it is not. Data in table excludes columbium and tantalum bearing tin concentrates and slags.

[2] In addition to the countries listed, Spain, South-West Africa and the U.S.S.R. also produce columbium and tantalum mineral concentrates, but information is inadequate to make reliable estimates of output levels.

[3] Exports.

[4] Less than ½ unit.

Copper

By Harold J. Schroeder [1]

World mine production of copper increased 10% to 7.31 million tons, a record high for the fifth consecutive year. The increase was broadly shared by almost all major producing countries. A number of new mine projects, notably in Papua New Guinea, Western Canada, Indonesia, the Republic of South Africa, and Zaire came onstream during the year.

In the United States, mine, smelter, and refinery outputs increased substantially from the strike-curtailed level of 1971 with smelter and refinery outputs from primary materials at record high quantities. Consumption of refined copper also increased significantly to the largest quantity since the record high of 1966. Foreign trade in unmanufactured copper was characterized by an increase in imports and a decline in exports. Changing market conditions were reflected in a price increase of 2¼ cents in February and a decrease of 2 cents in July for a yearend quotation of 50½ to 50¾ cents per pound for electrolytic wirebar copper.

[1] Reported actual consumption beginning with 1945. Prior to 1945 data are apparent consumption of refined copper.

[2] American Metal Market price for electrolytic copper in New York until April 1955; thereafter, delivered U.S. destinations basis; and exclusive of bonus payments of the Office of Metals Reserve under the Premium Price Plan during the period Feb. 1, 1942, to June 30, 1947.

Legislation and Government Programs.—The total copper in the national stockpile on December 31, 1972, was 60,112 tons of oxygen-free, high-conductivity (OFHC) copper, 7,067 tons of copper in beryllium-copper master alloys, and 191,480 tons of copper in "other" classifications, for a total of 258,659 tons, 33% of the objective of 775,000 tons.

The Office of Minerals Exploration (OME) continued to offer up to 50% government participation in the authorized cost of exploration for copper deposits. There were no contracts executed in 1972 that involved copper.

Regulations were amended to change the base period from calendar year 1969 to calendar year 1971 for calculating set-asides for certain brass mill, wire mill, and foundry products retained under the program of copper controlled materials for defense purposes.

The duty on imported unmanufactured copper was reduced to 0.8 cent per pound, effective January 1, 1972, as the last step in the progressive reduction of the rate of duty in accord with the Kennedy Round Trade Expansion Act of 1962. Duties suspended by public laws since 1966 were reimposed when the latest extension to Public Law 91–298 expired June 30, 1972.

DOMESTIC PRODUCTION

PRIMARY COPPER

Mine Production.—Domestic mine production was 1.66 million tons, an increase of 9% from the strike-curtailed output of 1971, but 3% below the record high of 1970. Principal copper-producing States were Arizona, with 55% of the total, Utah (16%), New Mexico (10%), Montana (7%), Nevada (6%), and Michigan (4%). These six States accounted for 98% of the total domestic production.

Open pit mines accounted for 80% of mine output and underground mines for 20%. The production of copper from dump and in-place leaching, largely recovered by precipitation with iron, was 171,000 tons or 10% of mine output. Total copper recovered by leaching methods was 253,500 tons, of which 221,900 tons was precipitated with iron and 31,600 tons was electrowon.

Duval Corp., a subsidiary of Penzoil Co., operated the Duval Sierrita mine near Tucson, Ariz., for the second full year and in November and December achieved an average daily operating rate of 84,600 tons of ore. Duval's Esperanza property adjacent to Sierrita remained closed during the year owing to a shortage of smelting capacity to treat the stockpiled concentrates, but is expected to resume production in 1973.

The Anaconda Company operated mines in Arizona, Montana, and Nevada with production of 233,471 tons of copper, a recovery from the strike-curtailed output of 182,014 tons in 1971. The Twin Buttes, Ariz., open pit mine produced 66,486 tons of copper from sulfide ore. Approximately 20 million tons of stockpiled oxide-type ore will be processed in a 10,000-ton-per-day leach-electrowinning plant scheduled for completion in 1975. Output capacity of the plant will be 30,000 tons of electrolytic copper a year. In Montana, the underground mines contributed 20,833 tons and the Berkeley pit 104,934 tons of copper. As part of an expansion program the concentrator capacity is being increased from 40,000 to 50,000 tons per day and plans are underway to develop open pit operations in an area east of the Berkeley pit. Production at the Yerington, Nev., property was 41,218 tons compared with 42,541 tons the preceding year. Exploration and feasibility planning continued toward development of a large underground mine at Carr Fork in the Bingham District of Utah with anticipated production by 1977.

Kennecott Copper Corp. operated mines in Arizona, Nevada, New Mexico, and Utah; these mines produced a combined total of 460,600 tons of copper, compared with 456,100 tons in strike-affected 1971. The Utah Copper Div. accounted for 258,000 tons of the total followed by the Ray Mines Div. (Arizona) with 90,200 tons, the Chino Mines Div. (New Mexico) with 73,400 tons, and the Nevada Mines Div. with 39,000 tons. A limiting factor on mine copper production was smelter throughput, which was adversely affected by operating problems and construction of plant modifications to meet anticipated air pollution control regulations.

The American Smelting and Refining

Company (Asarco) operated three copper mines in the vicinity of Tucson, Ariz. The Mission unit produced 45,400 tons of copper in concentrate compared with the 1971 strike-curtailed output of 40,600 tons. The Silver Bell unit was unaffected by the 1971 strike and output increased slightly to 23,600 tons of copper in concentrate and precipitates. Production at the San Xavier mine was limited to copper-bearing flux ore for use at Asarco's Hayden smelter. Two new Arizona copper mining projects were initiated by Asarco in 1972. One project was construction of a leach plant to treat 4,000 tons per day of copper oxide ore from the north mine at San Xavier. Startup is scheduled during the first quarter of 1973. The second project is the Sacaton mine at Casa Grande, with an open pit mine and mill expected to be in operation early in 1974 and underground mining of deeper ore anticipated in 1979. The combined annual capacity of both projects will be 33,000 tons of copper contained in concentrate and precipitates.

Mines of the Phelps Dodge Corp. produced 305,400 tons of copper compared with a record high 313,500 tons in 1970 and the strike-affected output of 281,200 tons in 1971. Of the output 119,800 tons was derived from Morenci, Ariz., 57,900 tons from Ajo, Ariz., 48,500 tons from Bisbee, Ariz., 78,800 tons from Tyrone, N. Mex., and 400 tons from other sources. Expansion of the Tyrone mine from a capacity of 60,000 to 100,000 tons per year was substantially completed by August. The Tyrone expansion will be offset by probable closure of the Bisbee open pit operations in late 1973 and of the Bisbee underground operations shortly thereafter. Stripping continued at the Metcalf property near Morenci and construction of the concentrator is underway with initial output planned for early 1975. Rated capacity of the Metcalf project is 50,000 tons of copper per year. A preliminary development program at Safford, Ariz., was in progress to determine the feasibility of mining a deep ore body containing an estimated 250 million tons of ore with an average grade of 0.92% copper. Work included a haulage drift into the ore at a depth of 1,800 feet and mining a test block to determine the caving characteristics of the ore.

Cities Service Co., through its North American Chemicals and Metals Group, operated copper mines in Arizona and Tennessee that produced 44,900 tons of copper, compared with 44,000 tons in 1971. Preproduction stripping and mill construction were begun for development of the large, low-grade Pinto Valley copper deposit in the Miami, Ariz., area, with initial output scheduled for mid-1974. A production rate of 40,000 tons of mill feed per day is expected by early 1975. Plans were underway for underground mining of the high-grade Miami East ore body at a depth of 2,500 to 3,700 feet; production is scheduled to start in 1974 and to reach a level of 2,000 tons per day by 1978.

The White Pine Michigan operations of White Pine Copper Co. milled a record high 8,250,000 tons of copper ore averaging 1.0% copper with an 85.77% copper recovery in concentrate. The mine continued to experience adverse ground conditions, particularly in the vicinity of a major fault, which resulted in monthly variations of ore mined per day from approximately 20,000 to 25,000 tons. Research on mining methods and practices to overcome the roof control problem included tests of longwall mining and use of resin-anchored rock bolts.

Magma Copper Co. operated the San Manuel and Superior mines in Arizona throughout the year. The San Manuel underground mine demonstrated its ability to produce up to 65,000 tons of ore per day. At Superior, the program of doubling mine and mill capacity to 3,300 tons of ore per day is ahead of the original schedule and anticipated to be in operation during the last quarter of 1973. Output of copper in concentrate will be increased from a rate of 20,000 to 40,000 tons per year.

The Inspiration Consolidated Copper Co. operated the Thornton, Live Oak, Red Hill, and Black Copper mines in the vicinity of Inspiration, Ariz.; 14.3 million tons of waste and 7.8 million tons of ore were mined. The ore processed in the plant yielded 41,158 tons of copper. An additional 9,588 tons was recovered from leaching dumps and mined-out areas and by heap leaching. At the Ox Hide mine 2.4 million tons of oxide ore was mined and 4,475 tons of copper was recovered by leaching. At the Christmas open pit mine, southeast of Miami, Ariz., 9.1 million tons of waste and 1.9 million tons of ore was mined; 10,611 tons of copper was recovered. Total production of copper by the company was 65,832 tons, 17% above the strike-curtailed output of 1971.

Pima Mining Co. produced 79,500 tons of copper in concentrate from milling 18.7 million tons of copper-molybdenum ore from its mine south of Tucson, Ariz. A 35% expansion in milling capacity was completed early in the year and by yearend exceeded rated capacity. At the end of 1972 ore reserves totaled 240 million tons averaging 0.5% copper.

Bagdad Copper Corp. at its Arizona mine, produced 12,230 tons of copper in concentrate and 6,700 tons as cathode copper, the latter obtained from oxide ore by a leach-electrowinning process. Grade of sulfide ore mined in 1972 averaged 0.70% copper. Reserves for the present operation consist of 38 million tons of sulfide ore with a copper content of 0.66%, overlain by approximately 12.5 million tons of copper oxide material and overburden. The company has under consideration a planned expansion program to increase the mining rate fivefold to 30,000 tons of sulfide ore per day. Sulfide reserves for the expanded operation which include the reserves for the present operation are estimated to be 303 million tons averaging 0.47% copper. Total oxidized copper material are 40 million tons of approximately 0.36% copper overlying the sulfide ore plus 77 million tons of 0.21% acid soluble copper now stockpiled in waste dumps.

The Bruce Mine Div. of Cyprus Mines Corp. operated its underground copper-zinc mine near Bagdad, Ariz., at near capacity during 1972. New milling equipment and higher ore grade increased output 36% to 3,400 tons of copper in concentrate produced from processing 96,200 tons of ore averaging 3.92% copper and 13.7% zinc. Known ore reserves are sufficient for at least 5 years at the present operating rate.

Ranchers Exploration and Development Co. moved about 3.9 million tons of overburden and 4.5 million tons of ore at their Arizona Bluebird property. The ore, with an average grade of 0.44% copper, was placed on dumps for processing by a leaching-solvent extraction-electrowinning method of recovery. Production of refined copper cathodes by this method increased 18% to a record high 7,000 tons. A leach-precipitation plant to produce cement copper from about 300,000 tons of stockpiled mixed oxide-sulfide ore containing about 2% copper at the Big Mike copper property near Winnemucca, Nev., was placed in operation. Additional ore in place is available for treatment at the plant. In March, Rancher's initiated an in situ leaching operation at the Old Reliable deposit near San Manuel, Ariz., with a blast using 4 million pounds of explosives to fracture an ore deposit with reserves estimated at 4 million tons of 0.74% copper. Leach solution was introduced at the surface in August and precipitation of the copper from the pregnant liquor was begun by yearend. It is estimated that about 15,000 tons of copper will be recovered by this method over a 5-year period.

Hecla Mining Co. reached the 6,600-foot point of a planned 15-degree decline of 7,500 feet to develop their Arizona Lakeshore copper mine. Crosscuts and development headings were being driven into both the sulfide and oxide ore zones. The concentrator, roast-leach-electrowinning, and vat-leach pilot plants operated successfully during the year and provided data for engineering design of the commercial plants scheduled for 1975 production. Design capacity is 69,000 tons per year of copper, 31,000 tons as cathode and 38,000 tons as cement copper. The yearend ore reserve estimate was 470 million tons averaging 0.75% copper.

UV Industries Inc. operated their Continental mine near Bayard, N. Mex., and milled approximately 875,000 tons of copper ore. The company completed a mill expansion project during the year bringing total milling capacity to 7,500 tons per day.

Smelter Production.—Output of copper at primary smelters in the United States was 1.76 million tons, a 12% increase from the strike-curtailed output of the previous year and a new record high quantity. The record high output was achieved despite some disruptions to production including curtailment of operations at several smelters to maintain required air quality standards during periods of adverse meteorological conditions.

Asarco's three copper smelters were not able to operate at full capacity, principally due to curtailment of production for air quality control purposes, and to a smaller degree, to shortages of natural gas during severe winter weather. Also, major breakdowns of air compressor equipment at the Hayden smelter caused a production cutback of approximately 30% for 3 months. New sulfuric acid plants were brought into operation at the Hayden and El Paso smelters and a 200-ton-per-day liquid sulfur dioxide plant was scheduled for completion in late 1973 at the Tacoma smelter. Upon completion of the Tacoma project, more than 50% of the sulfur input to the three smelters will be recovered. The quality of the ambient air will be further improved at Hayden by construction in 1973 of a 1,000-foot stack and installation of a new "closed loop" sulfur dioxide monitoring system similar to the systems now operating at the Tacoma and El Paso plants.

Anaconda's smelter renovation program, to improve environmental conditions and increase capacity from 30 to 35 million pounds of copper per month continued towards the scheduled second-quarter-1973 completion date. Kennecott awarded contracts for construction of converter hoods, ductwork, an electrostatic precipitator, and an acid plant at the Hurley, N. Mex., smelter; the company installed a fourth converter and made plans for constructing a 750-foot stack to disperse emissions at the McGill, Nev., smelter.

Phelps Dodge began construction of a new smelter in Hidalgo County, N. Mex., in order to have smelter capacity available for Tyrone concentrate when the Morenci smelter will be required to process the new Metcalf concentrate. The company was also constructing emissions control facilities including new acid plants at their Ajo and Morenci, Ariz., smelters.

Magma Copper Co. experienced some output restrictions at its San Manuel smelter owing to startup problems with the reverberatory furnace, the converter hoods, and a new automatic anode casting wheel installed during the recent expansion program. Magma is proceeding with construction of a $30 million converter gas collection and cooling system and a sulfuric acid plant, which, in conjunction with an air monitoring system, is expected to achieve required ambient air quality standards.

Inspiration Consolidated Copper Co. continued work on a $50 million construction program to replace much of the existing smelter at Miami, Ariz. The program, scheduled for completion in 1973, will replace the existing reverberatory furnace with an electric furnace, the present converters with new siphon-type converters, and provide new sulfuric acid production facilities.

White Pine Copper Co. operated a slag recovery plant from May through December that treated 560,000 tons of slag and recovered more than 3 million pounds of copper for return to the smelter compared with the total 1972 smelter output of 140 million pounds of copper.

Refinery Production.—Production of refined copper from primary materials was 1.87 million tons, a record high and 6% above the previous high of 1970. Refined copper produced from scrap was 423,200 tons compared with 400,700 tons in 1971. Total production of refined copper in the United States was 2.29 million tons, derived 81% from primary and 19% from scrap sources.

Copper Sulfate.—Copper sulfate was produced from primary and/or secondary metal by companies with plants located as follows:

Company	Plant location
The Anaconda Company	Great Falls, Mont.
Chevron Chemical Co	Richmond, Calif.
Cities Service Co	Copperhill, Tenn.
M.C.S. Corp	Baltimore, Md.
Phelps Dodge Refining Corp	Laurel Hill, N.Y. El Paso, Tex.
Van Waters & Rogers Inc	Wallace, Idaho. Midvale, Utah. Metaline Falls, Wash.

Copper sulfate production increased 10% to 38,050 tons, a partial recovery from the 1971 slump to the smallest quantity since 1935. Shipments were slightly less than production and ending stocks were 5,800 tons. Of the total 37,960 tons shipped, producers' reports indicated that 14,030 tons was for agricultural uses, 22,400 tons was for industrial uses, and 1,530 tons was for other uses.

Byproduct Sulfuric Acid.—Sulfuric acid was produced at six copper smelters from the sulfur contained in offgases, and output increased for the fifth consecutive year from 803,300 to a record high of 1,010,600 tons, on a 100% acid basis. Facilities for sulfuric acid production were placed in operation late in the year at the El Paso, Tex., smelter of Asarco. New sulfuric acid plants were under construction or in an advanced planning stage at copper smelters at Ajo, Ariz., Anaconda, Mont., Hurley, N. Mex., Miami, Ariz., Morenci, Ariz., McGill, Nev., and San Manuel, Ariz.

SECONDARY COPPER AND BRASS

Domestic recovery of copper in all forms from all classes of purchased scrap totaled 1.30 million tons in 1972, an 8% increase from the 1971 total and the largest quantity since 1969. Recovery from copper-base scrap increased from 1.18 to 1.28 million tons. Brass mills accounted for 44% of the recovered copper, primary producers for 28%, and secondary smelters for 23%. The remaining 5% was reclaimed at chemical plants, foundries, and manufacturers.

Consumption of purchased copper-base scrap in 1972 was 1.8 million tons consisting of 62% new scrap and 38% old scrap. The major categories of brass mill products, refined copper, and brass and bronze ingots obtained from scrap all registered substantial increases.

CONSUMPTION

Consumption of refined copper rose 10% to 2.24 million tons. This was the largest quantity since the record high of 1966 and reflected the greater activity of the general economy. Most of the consumption was at wire mills, which increased 15% to 1.53 million tons. The brass mills used 667,000 tons of refined copper, 2% more than in 1971.

Apparent withdrawals of primary refined copper on domestic account was 1.90 million tons compared with 1.62 million tons in 1971.

STOCKS

Stocks of refined copper at primary producers increased from 75,000 to 91,000 tons during January then trended down to 57,000 tons by yearend. Fabricators' stocks of copper in all forms declined erratically from 511,000 tons at the start of the year to 460,000 tons by yearend.

PRICES

Domestic producer price quotations for wirebar copper increased 2¼ cents in February and decreased 2 cents in July for a yearend quotation of 50¼ to 50½ cents per pound. Average weighted prices for domestic copper deliveries in 1972 was 51.2 cents compared with 52.0 cents for those in 1971. Prices on the London Metal Exchange (LME) increased from an average of 48.8 cents per pound equivalent for January to 52.5 cents for March, then declined erratically to 45.6 cents for November, and increased to 46.3 cents for December. The 1972 average was 48.5 cents, unchanged from the 1971 average.

FOREIGN TRADE

U.S. exports of unmanufactured copper, excluding the category of ash and residues, first reported in 1972, decreased 7% to 226,300 tons. The largest category, refined copper, was 182,700 tons compared with 187,700 tons the preceding year. Exports of ore, concentrates, matte, and blister decreased from 36,800 tons in 1971 to 26,200 tons, and exports of copper scrap declined 5% to 17,400 tons.

U.S. imports of unmanufactured copper were 415,600 tons, an increase of 16% and the largest quantity since 1968. The largest increases were for refined copper, which advanced 17% to 192,400 tons, and for ore and concentrates, which rose from 30,800 to 53,700 tons. Blister copper was slightly higher at 157,400 tons. Of the total imports Canada supplied 36%, Peru 22%, and Chile 14%.

WORLD REVIEW

World mine production of copper attained 7.31 million tons, a record high for the fifth consecutive year with most major producing countries contributing to the increased output. A number of new mining projects, notably in Australia, Western Canada, Indonesia, the Republic of South Africa, and Zaïre came onstream during 1972.

The United States continued to lead the world in mine production with 23% of the total, followed by Canada, Chile, and Zambia each with 11%, and the U.S.S.R. and Zaire with 10% and 6%, respectively.

Argentina.—Cía. Minera Aguilar, S.A., Argentina subsidiary of St. Joe Minerals Corp., announced discovery of a large copper deposit at Pachon, in the Province of San Juan. Based on limited drilling the estimated reserves are 88 million tons of 1% copper and 65 million tons of 0.65% copper ore. An access road to the remote location is under construction to permit additional drilling and underground exploration.

Cities Service Co. discontinued exploration of a potential copper-molybdenum ore body in Catamarca Province because mineralization was considered subeconomic. However, evaluation of other mineral prospects in northwestern Argentina continued.

Australia.—Mine production of copper in Australia was 203,930 tons, an increase of 6%. Mount Isa Mines Ltd. (ISA), 53% owned by Asarco, increased output 16% to a record high 132,000 tons of blister copper for the fiscal year ended June 30, 1971, as its expansion program moved towards a mine-mill-smelter productive capacity of 170,000 tons per year by mid-1973. Exploration drilling increased ore reserves to 156 million tons containing 3.0% copper.

Mount Lyell Mining and Railway Co., Ltd., for the year ended June 30, 1972, produced a record high 24,000 tons of copper in concentrate from 2.7 million tons of ore mined and milled. The transition of production from open pit to underground operations was proceeding smoothly with 41% of production for the year from underground mining; an almost total transition was expected by September 1972. Reserves in all ore zones were estimated at 36 million tons of 1.48% copper for proven ore and 7 million tons of 1.47% copper for probable ore.

Bougainville Copper Pty., Ltd., began production in April, 3 months ahead of schedule, from its Panguna copper deposit on Bougainville Island in the Territory of Papua New Guinea. Output for 1972 was 136,700 tons of copper in concentrate derived from milling 2.1 million tons of ore averaging 0.78% copper. Initial mining was in an enriched, mixed oxide-sulfide portion of the deposit. This large copper development, consisting of an open pit mine, a 90,000-ton-per-day concentrator, two towns, port facilities, a power station, and other ancillary facilities became operational just 8 years after the start of exploration and 3 years after the commencement of production development. Annual rated productive capacity is 162,500 tons of copper in concentrate to be shipped to smelters in Japan, West Germany, and Spain. The project is based on a porphyry copper deposit calculated to contain approximately 1 billion tons of ore grading 0.48% copper and 0.02 ounce of gold per ton.

Botswana.—Bamangwato Concessions, Ltd. (BCL), owned 85% by Botswana Roan Selection Trust, Ltd. (BRST), and 15% by the Botswana Government, continued development of the Selebi-Pikwe nickel-copper mining project and its related infrastructure. The capital cost of the mining project is estimated at $143 million and the cost of the related infrastructure at $71 million. Production is expected to start by early 1974 at an initial annual rate of 17,000 tons of refined copper, 19,000 tons of refined nickel, and 140,000 tons of sulfur. The Pikwe deposit, which has a higher nickel content than the Selebi deposit, will be developed first. Mining facilities at Selebi are expected to be started in 1977 for initial production in 1979. Proven and probable reserves for the Selebi-Pikwe deposits are estimated to total 45.7 million tons grading 1.20% nickel and 1.26% copper.

Canada.—Production of copper in Canada increased 11% to 800,600 tons to achieve a record high for the third successive year. Ontario produced 36% of the total, followed by British Columbia, with 31%; Quebec, with 22%; Manitoba, with 7%; and the remaining Provinces, 4%.

Falconbridge Nickel Mines Ltd. operated nickel-copper mines and treatment plants in the Sudbury, Ontario, area at near capacity during 1972. Metal deliveries were 28,200 tons of copper compared to 30,500 tons in 1971. The decline was owing to a lower copper content of the ores mined and treated. Ore reserves at yearend were 93 million tons averaging 1.33% nickel and 0.67% copper. Falconbridge's Opemiska Div. during its first full year of expanded operations mined and milled 1,157,000 tons of 2.2% copper ore, compared with 1,074,000 tons of 2.3% copper ore in 1971. Ore reserves at yearend were 6.9 million tons with an average grade of 2.46% copper.

Ecstall Mining Ltd., a subsidiary of Texas Gulf, Inc., mined 3.6 million tons of ore from the copper-lead-zinc-silver Kidd Creek mine near Timmins, Ontario, which yielded 45,550 tons of copper in concentrates. The underground mine development is expected to supply 2,000 tons of ore per day by the end of 1973 and to be capable of providing the entire concentrator feed of 10,000 tons per day, as the open pit will be gradually phased out of operation over the next several years.

The International Nickel Co. of Canada Ltd. (INCO) mined 19 million tons of nickel-copper ore from 14 mines in Ontario and Manitoba compared with 28 million tons from 18 mines in 1971. The ores mined were selectively those with higher than average copper content consequently the copper output did not decline as much as indicated by the curtailed ore production. Copper deliveries from the Copper Cliff refinery were 154,090 tons compared with the record high 170,150 tons in 1971. A plant constructed to process residues from the nickel refinery will recover electrolytic copper and has an annual rated capacity of 15,000 tons of copper. At yearend INCO estimated that proven ore reserves were 389 million tons containing 4 million tons of copper.

Noranda Mines Ltd. operated the Horne mine in Quebec, mining 690,000 tons of ore averaging 2.28% copper and 0.162 ounce of gold per ton. The mill recovered 95,000 tons of copper concentrate and 142,000 tons of pyrite concentrate. Sulfide ore reserves at yearend were 1.1 million tons grading 2.11% copper, sufficient to maintain production until June 1974. The company's Geco mine produced a record 1.8 million tons of copper-zinc-silver ore averaging 2.12% copper which yielded 36,000 tons of copper in concentrates. Noranda's smelter achieved a record high production of 236,000 tons of anode copper from smelting their own and custom concentrates. The $19 million construction program for the Noranda Continuous Smelting Process prototype, designed to treat 800 tons of copper concentrate per day, will be completed by March 1973.

Gaspé Copper Mines Ltd. operated the Needle Mountain and Copper Mountain mines and associated mills and smelter near Murdochville, Quebec. The Needle Mountain mine produced 17,500 tons of copper in concentrate from milling 1.6 million tons of ore averaging 1.17% copper. The Copper Mountain mine produced 15,700 tons of copper from milling 2.4 million tons of 0.78% copper. Feed to the smelter consisted of 236,800 tons from the Gaspé operation and 118,000 tons from custom sources for production of 63,800 tons of copper in anodes. A $108 million mine-mill-smelter expansion project was under construction with completion scheduled during 1973. The new facilities will triple the mining-concentrating capacity to 34,000 tons per day of sulfide ore, which will more than double the present output of copper in concentrate. In addition, leaching facilities for treatment of 5,000 tons per day of low-grade oxide ores will be built. The smelter expansion will add 27,000 tons per year of blister copper capacity and a sulfuric acid plant with a rated annual output of 300,000 tons, about half to be used in the copper-leaching operation.

Madeleine Mines, Ltd., operated their Quebec copper mine after the February 12 settlement of a labor strike. During the period of operations the mill treated 730,000 tons of 1.42% copper ore which yielded 9,725 tons of copper in concentrate. Development during the year included sinking a shaft to facilitate mining deeper sections of the reserves and provide access for further exploration. Reserves at yearend were 4.4 million tons with an average 1.17% copper content.

Hudson Bay Mining & Smelting Co., Ltd., milled 1.8 million tons of ore and produced 54,076 tons of refined copper. The refined copper output was double the

1971 quantity when operations were closed by a strike of 5 months duration. The company operated 10 mines along the Manitoba-Saskatchewan boundary, including the White Lake and the Ghost Lake copper-zinc-silver mines, which were brought into production in 1972, and the Flexar mine, which was closed in October when reserves were depleted. Total ore reserves at yearend were 17 million tons with an average grade of 2.95% copper, 3.3% zinc, and 0.57 ounce of silver per ton.

Sheritt-Gordon Mines Ltd. continued operation of the Fox and Lynn Lake mines in Manitoba. Combined output for the year was 20,500 tons of copper contained in concentrates, a nearly one-third reduction from the record high of 1971. The curtailed output was a result of difficulties encountered in mining a pillar of high-grade ore in the Fox mine. Reserves at the Fox property were estimated at 13.3 million tons averaging 2.01% copper and 2.23% zinc. Owing to changing ore characteristics and mining costs the company decided not to publish reserves for Lynn Lake until a study in progress is completed. Development of the Ruttan Lake property continued with initial production at an annual rate of 3.5 million tons of ore scheduled during the second quarter of 1973. Reserves were 51 million tons grading 1.47% copper and 1.61% zinc.

During the second full year of operation the mine of Granduc Operating Co. north of Stewart, British Columbia, produced 27,000 tons of copper in concentrate from 2.1 million tons of 1.35% copper ore. Operating and manpower problems continued to hamper output and the planned production rate of 7,000 tons of ore per day was not achieved until late in the year. Ore reserves at yearend were 39 million tons averaging 1.67% copper.

Similkameen Mining Co. Ltd., a subsidiary of Newmont Mining Corp., completed construction of mining facilities near Princeton, British Columbia. The project, which cost $71 million, began milling of ore from the open pit mine in April and reached the rated capacity of 15,000 tons per day by mid-August. Output for the year was 11,350 tons of copper in concentrate from milling 3.0 million tons of 0.44% copper ore. Ore reserves were estimated at 72 million tons averaging 0.53% copper.

Utah International Inc. shipped approximately 32,500 tons of copper in concentrates during the first full year of operation at their Island Copper mine on the northern end of Vancouver Island. The mill design capacity of 33,000 tons per day was not achieved, owing principally to unexpected ore characteristics that adversely affected the capacity of the autogenous grinding mills. Ore reserves are estimated at 280 million tons containing 0.52% copper and 0.025% molybdenum.

Anaconda Britannia Mines Ltd. produced 9,500 tons of copper in concentrate at their mine in British Columbia compared with 8,300 tons in 1971. The increased output was related to new development work completed in 1970, which increased the rated annual productive capacity to 10,000 tons of copper.

Brenda Mines Ltd. delivered 9.5 million tons of ore to the concentrator averaging 0.21% copper and 0.06% molybdenum. Metal recoveries in concentrates were 90% for copper and 86% for molybdenum. An additional 3.3 million tons of low-grade ore was stockpiled for future treatment and 5.9 million tons of waste was stripped from the deposit.

Bethlehem Copper Corp. Ltd. mined approximately 6 million tons of 0.54% copper ore from the Jersey and Huestis open pit mines at Highland Valley, British Columbia, and produced concentrates containing 29,100 tons of copper. In November, mining of the Jersey ore body reached design limits and mining was discontinued. Plans are being formulated to develop the J-A ore body 2 miles south of the operating mines, containing an estimated 300 million tons of copper-molybdenum ore with an average grade of about 0.45% copper equivalent. Reserves for the presently operated property are 39 million tons of 0.56% copper, for the Lake zone project 190 million tons of 0.48% copper, and for the Maggie ore zone at least 200 million tons of 0.40% copper equivalent.

Lornex Mining Corporation Ltd. began commercial production on October 1 at their large, low-grade copper-molybdenum property in the Highland Valley of British Columbia. The mill has a rated capacity of 38,000 tons of ore per day, which is calculated to yield 55,000 tons of copper in concentrate annually. Ore reserves are estimated to be 293 million tons with an average grade of 0.427% copper and 0.014% molybdenum.

Gibralter Mines Ltd. commenced operations at their copper-molybdenum deposit in the Cariboo District of British Columbia in March and the mill treated a total of 11.2 million tons of ore at an average grade of 0.46% copper which yielded a total of 41,000 tons of copper in concentrate. The rated 30,000-ton-per-day capacity of the concentrator was quickly achieved and after April 1 averaged 39,500 tons. Copper recovery, at 80.4%, was adversely affected by the oxide copper content of the ore being mined. A total of 26.4 million tons of ore, waste, and overburden or an average rate of 77,300 tons per day was moved. Studies indicated the daily rate should be increased to 120,000 tons to balance maximum concentrator capacity and equipment was being acquired toward that goal. At yearend the minable ore reserves, at a cutoff grade of 0.25% copper, were estimated at 347 million tons grading 0.37% copper.

Craigmont Mines Ltd. in the fiscal year ended October 31, 1972, produced 23,600 tons of copper in concentrate from 1.9 million tons of ore containing 1.34% copper from their mine near Merritt, British Columbia. Average production from the sublevel caving operation was a record high of 4,850 tons per day. Ore reserves, at a cutoff grade of 0.7% copper, are estimated at 10.3 million tons grading 1.77% copper.

Bell Copper Co. initiated production in October at their Babine Lake, British Columbia, property. Open pit mining consisted of 2.5 million tons of stripping, 0.9 million tons of low-grade ore stockpiled for future treatment, and 1.2 million tons of ore averaging 0.71% copper for delivery to the concentrator. The concentrator, with a rated capacity of 10,000 tons per day, averaged 9,200 tons during the startup period and produced 15,400 tons of concentrate containing 4,150 tons of copper with an average 82.5% copper recovery.

Coast Copper Co., Ltd., suspended operations at its Benson Lake mine on Northern Vancouver Island in November because of rising costs and unsatisfactory market conditions. During the 10 years of operations 2.8 million tons of ore were mined to produce 157,000 tons of copper concentrate.

Chile.—Litigation concerning the amount of compensation to be paid to the former owners of copper mines that were nationalized in 1971 continued throughout the year. Appeals by The Anaconda Company and Kennecott Copper Corp. asking compensation for their equities in the expropriated Chuquicamata, El Salvador, and El Teniente properties were rejected by the Chilean Copper Tribunal in August. Kennecott has initiated actions to contest the terms of the expropriation in the courts of several other countries. The amount due Cerro Corp. for its equity in the Andina property was set by the Copper Tribunal and negotiations were in progress to set the time and terms of payment. Anaconda and Kennecott began litigation with the State-owned Chilean copper company (Corporation Del Cobre) in Chilean and United States courts with regards to the enforcibility of promissory notes, now in default, that were given by Chile to Kennecott in 1967 and to Anaconda in 1969 for 51% interest in the El Teniente, Chuquicamata and El Salvador properties. The Overseas Private Investment Corp. (OPIC) purchased notes guaranteed by Chile and issued to Kennecott to help finance development of the El Teniente mine. Claims by Anaconda to OPIC for insurance payment of the $159 million in defaulted notes were refused and the claims have been submitted to binding arbitration as provided in the insurance contract.

Copper production was an estimated 798,900 tons, up 1% from that of 1971. Production from the large mines was as follows: Chuquicamata, 258,600 tons compared with 274,000 in 1971; El Teniente, about 200,000 tons compared with 155,000; El Salvador, 93,300 tons compared with 92,000; Exótica, 34,400 tons compared with 39,000; and Andina, 59,400 tons compared with 58,200.

Large plant expansions made immediately prior to nationalization failed to significantly increase production because of resignations of supervisory and technical personnel and shortages of equipment, repair parts, and supplies.

Production began from the Sagasca property late in 1972 with about 5,500 tons of copper in precipitate being shipped. The smelter treating El Teniente concentrates is being enlarged to 310,000 tons of copper per year by the addition of a new reverberatory furnace scheduled for completion in 1973. Studies were made of the Exótica vat-leaching plant where output has remained far below design capacity owing to unexpectedly large quantities of impurities in the leach solution. A decision was reached to add a solvent extraction circuit to provide clear solution for electrowinning. Construction was begun on a subsmelter in Vallenar with completion expected in 1973. The matte produced will be shipped to other smelters for conversion into blister copper.

Colombia.—The Colombian Government announced discovery of a copper deposit in the Department of Antioquia near the border of the Department of Chocó. The discovery was a direct outgrowth of assistance to the Colombian Governmant by the U.S. Agency for International Development (AID). In the preliminary report the deposit is estimated at 625 million tons with an average grade of 0.7% copper. Further exploration and a feasibility study will be required to determine the economic significance of the discovery.

Cyprus.—The Cyprus Island Div. of Cyprus Mines Corp. operated open pit mines at Lefka and Skouriotissa and a pressure-leach plant for reprocessing of mill tailings. Output of copper contained in concentrates and precipitates totaled about 9,750 tons. Milled ore averaged 1.3% copper but reserves of this grade were nearly exhausted. However, a deposit of lower grade (0.9% copper) in the Skouriotissa area with reserves estimated to extend the life of the mining operations about 5 years is under development.

Finland.—Copper output increased 23% to 38,400 tons. Principal producing mines were the Outokumpu with 19,600 tons, the Pyhasalmi with 5,300 tons, the Vihanti with 3,000 tons, and the Virtasalmi with 2,300 tons.

Indonesia.—Freeport Indonesia Inc., a subsidiary of Freeport Minerals Co., completed development of the 11,500-foot-altitude Ertsberg copper deposit in West Irian and initial production began late in 1972. The $150 million project is designed to operate at an annual production rate of 2.5 million tons of ore yielding about 65,000 tons of copper in concentrate plus recoverable quantities of gold and silver. Proven reserves are 33 million tons of ore averaging 2.5% copper, and 0.025 ounce gold and 0.265 ounce silver per ton. There are surface indications of additional mineralization in the vicinity of the Ertsberg deposit which will be explored.

Iran.—Sar Cheshmeh Copper Mining Co., an Iranian Government-owned company, signed a technical assistance agreement with The Anaconda Company for services to develop a $400 million copper mine and metallurgical complex in southern Iran. The operation will produce approximately 145,000 tons of copper per year about 4 years after the start of construction. Reserves upon which the project is based are 400 million tons averaging 1.12% copper. Substantial reserves of somewhat lower grade ore are indicated to exist in the area.

Malaysia.—The Mamut Mines Development Co., a consortium of Japanese firms in a joint venture with the Sabah Government and other Malaysian interests, continued development of a copper deposit near Mamut, Sabah. Production is scheduled for early 1975 at the rate of 18,000 tons of ore per day. Reserves are given as 80 million tons averaging 0.6% copper.

Mauritania.—Société Minière de Mauritanie (SOMIMA), 33.5% owned by Charter Consolidated Ltd., continued to experience delays in bringing their mine at Akjoujt into production. Output of the oxide ore deposit, minable by open pit methods, is concentrated in a plant using the Torco segregation process developed by the Anglo American Corp. of South Africa group. Design capacity of the plant is 30,000 tons of copper per year. The process has been satisfactorily demonstrated but the selected equipment requires extensive modification due to the difficult nature of the ore and the stresses of the desert climatic conditions.

Mexico.—Asarco Mexicana, S.A., increased the output of blister copper 42% to 36,000 tons. The gain was largely due to the first full year of operation of the Inguarán mine in the State of Michoacán. The company began construction of a new 45,000-ton-per-year refinery at San Luis Potosi. Cía. Mexicana de Cobre, S.A., 49% owned by Asarco Mexicana, continued studies relating to financing and development of a porphyry copper deposit at the La Caridad propety near Nacozari in the State of Sonora.

Compañía Minera Nacozari, S.A., operated the Cananea mine and smelter to produce 44,574 tons of blister and refined copper, an 11% increase. An expansion program in progress is expected to increase output each year until attainment of 70,000 tons in 1976.

Panamá.—Canadian Javelin Ltd. announced that the Cerro Colorado exploration project in western Panamá indicated a major porphyry copper deposit in excess of 1 billion tons averaging 0.6 to 0.7% copper. Feasibility studies to develop the ore body are in progress. The Cerro Colorado deposit is located about 90 miles west of the Petaquilla deposit, discovered in 1968 by a United Nations technical mission and estimated to contain from 200 to 300 million tons averaging 0.6% copper.

Peru.—Production of Southern Peru Copper Corp., in terms of blister copper produced and export of copper in concentrates, was 148,300 tons compared with 141,200 tons in 1971. Approximately 40,000 tons of concentrate production from the Toquepala mine was exported owing to curtailment of production at the Ilo smelter, which lost 43 work days by strikes. Cerro Corp. operations were relatively free of work interruptions and production inceased 16% to 52,130 tons of copper at its La Oroya smelter, with 39% of the output from purchased ores.

Minero Peru, a Peruvian Government entity, and the Japanese Mitsui Furukawa Group signed a contract for construction of a copper refinery at Ilo. The facility, scheduled for operation in 1975, will have a capacity of 150,000 tons of electrolytic copper per year. A letter of intent was signed by Minero Peru and a consortium of five Japanese companies to conduct a $2 million feasibility study for exploitation of the Michiquillay copper deposit in the Department of Cajamarca. The deposit has ore reserves estimated at 620 million tons grading 0.72% copper. However, the isolated location and a lack of basic infrastructures such as roads and electricity has been a deterrent to development of a viable operation. Minero Peru also announced discovery of a large porphyry copper deposit in the Department of Lambageque in northern Peru. This is the first significant discovery of copper in this area and preliminary exploration places the size between 50 and 300 million tons.

Development of the Cuajone mine by Southern Peru Copper Corp. continued during 1972 with expenditures of approximately $37 million, bringing the total investment at yearend to $83 million. Principal work accomplished during the year was the driving of 11,450 feet of railroad tunnel, removal of 20 million tons of overburden, and site preparation for the concentrator. A work plan was filed for expenditure or commitment of $48 million during 1973 as the next step in this $500 million project.

Compañía Minera del Madrigal, a subsidiary of Homestake Mining Co., brought the Madrigal copper-lead-zinc mine in southern Peru into operation in April. Output from the 500-ton-per-day mill and the ore grade during the first year of operation were below expectations. However, construction in progress is directed towards improving efficiency of production.

Philippines.—Twelve mining companies produced 226,000 tons of copper in concentrates and direct-shipping-grade ore, compared with 217,800 tons the previous year. Atlas Consolidated Mining & Development Corp., the largest copper producer in the Philippines, in the first full year of operation after completion of their mill expansion, increased output 14% to 88,700 tons of copper in concentrate. The second largest producer, Marcopper Mining Corp., produced 48,900 tons of copper from processing 7.6 million tons of ore containing 0.70% copper. Minable ore reserves are 118 million tons of 0.59% copper. Other major producing companies were Marinduque Mining and Industrial Corp., Lepanto Consolidated Mining Co., and Philex Mining Corp., with outputs of 34,700 tons, 28,600 tons, and 22,900 tons, respectively.

Poland.—A large expansion program at the Lubin and Polkowice mines and the associated smelter-refinery plants at Glogow and Legnica increased annual productive capacity to about 150,000 tons of copper. Continuation of the expansion program calls for development of a third large mine called Rudna, enlargement of the Glogow smelter-refinery and construction of a new refinery at Zukowice.

Rhodesia, Southern.—M.T.D. Mangula Ltd. during the year ending September 30, 1972, produced 18,800 tons of copper in concentrates and precipitates from the Mangula mine about 80 miles northwest of Salisbury. Concentrates containing 15,200 tons of copper were produced from milling 1.4 million tons of sulfide ore and precipitates containing 3,600 tons of copper were produced from treating 550,000 tons of an oxidized ore in the leach plant. Proved sulfide ore reserves are 15 million tons averaging 1.30% copper and oxidized ore reserves amount to 0.9 million tons of 0.75% oxide copper. Two new mines, Norah and Silverside, began operations near yearend. Proven sulfide ore reserves were 2.1 million tons of 1.30% copper at the Norah mine and 440,000 tons of 1.77% copper at the Silverside mine.

Lomagundi Smelting and Mining Ltd. produced 3,140 tons of copper in concentrates from mining and milling 330,000 tons of ore from the Alaska mine. The Shackleton mine yielded 10,050 tons of copper in concentrates from 570,000 tons of 1.90% copper ore. Reserves at yearend were 550,000 tons of 1.78% copper at the Alaska mine and 535,000 tons of 1.98% copper at the Shackleton mine.

Gwai River Mines Ltd. produced 2,500 tons of copper in concentrates from mining and milling 215,000 tons of 1.33% copper ore. Proved ore reserves were 130,000 tons of 1.31% copper.

South Africa, Republic of.—O'okiep Copper Co. Ltd. milled 3.5 million tons of ore with an average grade of 1.28% copper from eight producing mines, which yielded 40,700 tons of blister copper. Exploration increased reserves from 27.6 to 28.0 million tons of ore averaging 1.56% copper.

Palabora Mining Co. Ltd. increased output 12% to 110,200 tons of copper. Ore milled was 21.3 million tons of 0.56% copper compared with 21.0 million tons of 0.57% copper in 1971.

Messina (Transvaal) Development Co. mined and milled 1.2 million tons of 1.13% copper ore from the Messina mine, which yielded 12,100 tons of copper in concentrates. The tonnage of proved ore reserves remained little changed at 5.9 million tons but the grade improved from 1.38 to 1.44% copper.

Africa Triangle Mining Prospecting and Development Co., a holding company formed by Anglo-Vaal, Middle Witwatersrand, and United States Steel Corp., initiated production at their copper-zinc ore deposit near Prieska in northwestern Cape Province in late 1972, well ahead of schedule. It is anticipated that production will attain a rate of 110,000 tons of ore per month by early 1973 and increase to the planned rate of 250,000 tons per month during the second half of 1974. Proven reserves are estimated to be 25 million tons grading between 1.5 to 2.0% copper and about 3% zinc.

South-West Africa, Territory of.—The Tsumeb Corp. Ltd. operated the Tsumeb mine at a reduced level owing to first-quarter strikes; and quantity of ore milled was reduced 16% to 484,000 tons averaging 3.37% copper, 11.49% lead, and 3.20% zinc. The strike did not affect the Kombat mine and 416,000 tons of ore averaging 1.30% copper and 1.47% lead was mined and milled. The curtailed output at the Tsumeb mine and a lower copper content in ore milled at the Kombat mine was reflected in a reduction in blister copper produced at the smelter from 29,300 tons in 1971 to 28,800 tons in 1972. Yearend ore reserves were 5.8 million tons averaging 4.63% copper, 8.98% lead at the Tsumeb mine and 1.5 million tons averaging 1.96% copper and 3.11% lead at the Kombat mine.

Oamites Mining Co. Ltd., operated the Oamites mine for its first full year and produced 5,000 tons of copper in concentrate from milling 353,000 tons of 1.39% copper ore. A general labor strike in January and other startup problems hampered output but by yearend the rated capacity of 50,000 tons of ore per month was achieved.

Uganda.—In June the corporate income tax rate for mining companies was reduced from 40 to 22.5% and the copper export tax was abolished. Kilembe Mines, Ltd. 70% owned by Falconbridge Nickel Mines Ltd. (Canada) processed 90,700 tons of ore to produce 14,200 tons of blister copper compared with 17,300 tons in 1971. Ore reserves at yearend in the proven and probable category were estimated to be 6.2 million tons of 1.97% copper.

Zaire.—La Générale des Carrières et des Mines du Zaïre (Gécamines), the Government-owned mining company, increased copper output 6% to 473,000 tons. The greater output represents a step in an expansion program designed to increase Gécamines', annual copper producing capacity to 500,000 tons by 1974 and to 660,000 tons by 1980.

The joint Japanese-Congolese concern,

Société de Développement Industriel et Minier du Zaire (SODIMIZA) initiated production in October at the Mushoshi mine in Shaba Province. Designed capacity of the mine is 58,000 tons per year with a planned increase to 68,000 tons during 1976. Another mine at Tshinsenda is scheduled to be brought into production at a 68,000-ton-per-year rate during 1976. Ore reserves are estimated to be 110 million tons of 3.5% copper at Mushoshi and 35 million tons of 5.5% copper at Tshinsenda

Société Minière de Tenke-Fungurume (SMTF), a consortium of companies which includes Amoco Minerals Co., (subsidiary of Standard Oil Co. of Indiana), Charter Consolidated Ltd., and Leon Tempelsman & Son Inc., continued exploration work in their concession area of Shaba Province. SMTF announced reserves at the end of 1972 of 50 million tons with an average content of 5.5% copper and 0.44% cobalt. Plans are to construct a mining-milling-refining complex with the related infrastructure costing $300 million for production in 1977 at an annual rate of 150,000 tons of copper.

Zambia.—Copper production in 1972 was 790,500 tons compared with 718,300 tons in 1971.

Nchanga Consolidated Copper Mines Ltd. (NCCM), comprised of the Rokana, Chingola, and Konkola Divs., operated copper mines, a smelter, and a refinery. For the year ending March 31, 1972, output was 442,300 tons of refined copper, a modest increase in the rate of production from the preceding 15-month period. The target for the following year is 470,000 tons. At the Rokana Div. construction was in progress for a plant to treat mixed sulfide and oxide ores, a third acid plant, and installation of periodic current reversal in the tankhouse to increase capacity. At the Chingola Div. the leach precipitation plant was commissioned in October 1971 and was approaching the planned production rate of 2,200 tons of copper per month. The solvent extraction-ion exchange process plant was under construction with scheduled completion in 1974. Shaft sinking continued at Konkola but inflow of water continued to be a problem. Pumping capacity has been increased to 390,000 cubic meters a day and a further increase to 620,000 cubic meters is planned. Geological and metallurgical test work continued at Kansanshi in preparation for reopening of that mine in 1973.

Roan Consolidated Mines, Ltd. (RCM), comprised of the Mufulira, Chibuluma, Chambishi, Kalengwa, and Luanshya mines produced 268,000 tons of refined copper in the year ended June 30, 1972, compared with 270,000 tons produced the previous year. Rehabilitation of the Mufulira mine is proceeding on schedule but output remained at less than half that anticipated before the 1970 cave-in.

Luanshya production was lower than that of the previous year owing to lower ore grade and bad ground conditions. Development of the Baluba section continued with output at the rate of 24,000 tons of copper per year to commence in January 1973. Subsequent expansion is planned to increase this rate to about 60,000 tons as other sections of Luanshya are depleted. The increase in production at Chambishi from 33,000 to 38,000 tons was made possible by use of spare concentrator capacity at Mufulira. The development of underground mining at Chambishi is proceeding with output scheduled for late 1973 at an annual rate of 26,000 tons of copper. This rate is to be increased to 52,000 tons as open pit operations are gradually phased out. The completion of the extension to the Chambishi concentrater is scheduled for the second half of 1973.

TECHNOLOGY

Articles published on copper resources included results of research correlating the regional distribution of porphyry copper deposits to the developing concept of orogeny at the margins of drifting crustal plates;[2] the application of induced polarization and resistivity surveys in exploration for copper deposits;[3] and the potential use of neutron activation analysis in qualitative logging for copper where coring is difficult.[4]

---

[2] Hodder, Robert W., and Victor F. Hollister. Structural Features of Porphyry Copper Deposits and the Tectonic Evolution of Continents. Canadian Min. and Met. Bull., v. 65, No. 718, February 1972, pp. 41–45.

A soil sampling survey conducted on a 1-mile grid pattern, over a 400-square-mile area of central Utah, indicated that the discovered anomalies would have indicated exploration targets for most of the existing mining districts, but that some might have been overlooked.[5] Two papers described mineral occurrences of potential copper-producing districts in Colorado and Wyoming.[6]

Research has been conducted on the use of geophysical techniques to monitor slope stability in large open pit mines.[7] An article describes the operating parameters of the sublevel caving mining method and the application of this method to a copper deposit characterized as a steeply dipping vein surrounded by incompetent rock.[8]

A design study on construction of a hypothetical copper concentrator for a typical southwestern United States location concluded that incorporation of functional design, large equipment, and outdoor type of construction could result in substantial savings when compared with the cost of conventional designs.[9]

Several review articles on copper metallurgy were published;[10] they included descriptions of flash smelting and of the continuous smelting processes under development in Australia, Canada, and Japan. A more detailed description[11] is given of a continuous smelting process for a semicommercial (20,000 tons per year) prototype plant placed in operation in November 1971.

The Smelter Control Research Association (SCRA) has reviewed its own and the utility industry experience with lime and limestone scrubbing systems for removal of sulfur from stack emissions.[12] It was concluded that the use of scrubbing systems could be effective but that considerable research and development will be required for design of commercial-scale units. Another article[13] reviewed research on the choice of refractory materials for reverberatory furnace construction, considering factors of structural strength and thermal shock, and corrosion requirements.

An article[14] described a 90,000-ton-per-year Japanese smelter commissioned in January 1972 that uses the flash smelting process. The facility is claimed to be efficient in the poduction of copper and permits control of sulfur emissions to levels well within the stringent air quality standards. Some of the new copper smelting processes require copper recovery from the converter slag to achieve acceptable overall efficiency, and research has been conducted in that area.[15]

Three types of X-ray analytical instrumentation were tested in their application for rapid identification in sorting scrap metals and for quantitative analysis to provide guidance in the melting and casting of alloys.[16]

Development and use of an electromotive force electrolyte probe which reliably monitors the oxygen content during the casting of refined copper was described.[17] Control of oxygen during casting is vitally important to obtain the desired physical properties of refined copper.

Research related to copper hydrometallurgy included: development of an electrochemical process employing a ferric chloride leach in a hot acidic environment followed by electrolysis and precipitation steps to produce copper, iron, and elemental sulfur;[18] development of a process to produce pure copper powder through roasting, ammoniacal leaching, distillation to the oxide, blending with prepared copper sulfide, chloridization, and then reduction;[19] the selective stripping of a high-purity copper sulfate solution suitable for electrolysis from a copper-nickel-cobalt ammoniacal leach solution;[20] the determination of mineral leaching rates and sulfate formation rates during oxygen pressure leaching in the temperature range straddling the melting point of sulfur;[21] and the discovery of a strain of bacteria with optimum activity in the vicinity of 60°C and capable of oxidizing sulfur and iron compounds that may improve leaching efficiency of chalcopyrite at the temperatures reached in the interior of copper waste dumps.[22]

A report was published on a study considering mutual substitutability of aluminum and copper in electrical, heat exchange, and other applications.[23] Several articles described properties and applications of wrought copper and copper alloys.[24] Research to produce beryllium-copper alloys by electrodeposition of beryllium on liquid copper cathodes was generally unsuccessful.[25]

Table 3.—Copper produced from domestic ores, by source

(Thousand short tons)

Year	Mine	Smelter	Refinery
1968	1,205	1,235	1,161
1969	1,545	1,547	1,469
1970	1,720	1,605	1,521

Table 12.—Copper precipitates (from dump or in-place leaching) shipped directly to smelters and copper ore leached (heap, vat, or tank) in the United States by State in 1972, with content in terms of recoverable copper

State	Precipitates shipped (short tons)	Recoverable copper content (pounds)	Ore leached (short tons)	Recoverable copper content (pounds)	Percent
Arizona	82,124	120,759,514	12,227,895	[1]114,965,689	0.47
Montana	31,316	49,514,860	--	--	--
Nevada	15,058	22,551,781	[2]4,850,856	[2]36,731,701	.38
New Mexico	35,305	55,143,788	([2])	([2])	--
Utah	57,214	93,928,415	604,842	13,286,408	1.10
Other States	67	87,292	--	--	--
Total	221,079	341,985,550	17,683,593	164,983,798	.47

[1] Includes 63,280,704 pounds of electrowon copper.
[2] Nevada and New Mexico combined to avoid disclosing individual company confidential data.

Table 13.—Copper ore smelted and copper ore concentrated in the United States, and average yield in copper, gold, and silver

Year	Smelting ore		Concentrating ore		Total				
	Thousand short tons	Yield in copper, percent	Thousand short tons [1]	Yield in copper, percent	Thousand short tons [1]	Yield in copper, percent	Yield per ton in gold, ounce	Yield per ton in silver, ounce	Value per ton in gold and silver
1968	383	2.46	[2]169,671	0.60	170,054	0.60	0.0024	0.056	0.21
1969	485	2.17	[3]204,704	.62	223,752	.60	.0028	.065	.23
1970	542	3.51	[3]235,586	.60	257,729	.61	.0023	.067	.20
1971	453	1.76	[3]222,121	.56	242,656	.55	.0022	.059	.18
1972	484	1.68	[3]248,663	.55	266,831	.55	.0019	.059	.21

[1] Includes some ore classed as copper-zinc and minor amount of tailings (1971 excludes tailings).
[2] Includes all methods of concentration: "Dual process" (leaching followed by flotation concentration), "LPF" (leach-precipitation-flotation), tank or vat leaching, heap leaching, and froth flotation.
[3] Excludes tank or vat and heap leaching. (See tables 8 and 12).

Table 14.—Copper produced by primary smelters in the United States

(Short tons)

Year	Domestic	Foreign	Secondary	Total
1968	1,234,724	31,754	84,821	1,351,299
1969	1,547,496	37,995	77,329	1,662,820
1970	1,605,265	36,073	78,897	1,720,235
1971	1,470,815	29,181	66,333	1,566,329
1972	1,649,130	41,263	69,017	1,759,410

Table 15.—Primary and secondary copper produced by primary refineries in the United States

(Short tons)

	1968	1969	1970	1971	1972
PRIMARY					
From domestic ores, etc.:[1]					
Electrolytic	1,018,246	1,296,749	1,359,751	1,274,084	1,520,943
Lake	78,304	76,417	66,091	57,218	70,025
Casting	69,375	95,723	95,341	79,221	89,444
Total	1,160,925	1,468,889	1,521,183	1,410,523	1,680,412
From foreign ores, etc.:[1]					
Electrolytic	219,726	225,714	215,088	167,218	160,781
Casting and best select	56,735	48,212	28,823	14,046	32,040
Total refinery production of primary copper	1,437,386	1,742,815	1,765,094	1,591,782	1,873,233
SECONDARY					
Electrolytic[2]	327,549	410,749	433,394	323,913	341,581
Casting	15,869	2,094	17,623	18,599	16,667
Total secondary	343,418	412,843	451,017	342,512	358,248
Grand total	1,780,804	2,155,658	2,216,111	1,934,294	2,231,481

[1] The separation of refined copper into metal of domestic and foreign origin is only approximate, as accurate separation is not possible at this stage of processing.

[2] Includes copper reported from foreign scrap.

Table 16.—Copper cast in forms at primary refineries in the United States

	1971		1972	
	Thousand short tons	Percent	Thousand short tons	Percent
Billets	154	8	118	5
Cakes	116	6	124	6
Cathodes	291	15	552	24
Ingots and ingot bars	175	9	218	10
Wire bars	1,168	60	1,181	53
Other forms	30	2	38	2
Total	1,934	100	2,231	100

Table 17.—Production, shipments, and stocks of copper sulfate

(Short tons)

Year	Production		Shipments	Stocks Dec. 31[1]
	Quantity	Copper content		
1968	43,784	10,946	43,648	3,380
1969	50,568	12,642	49,556	4,248
1970	45,352	11,338	40,324	8,812
1971	34,648	8,662	36,852	5,936
1972	38,052	9,513	37,964	5,828

[1] Some small quantities are purchased and used by producing companies, so that the figures given do not balance exactly.

Table 18.—Byproduct sulfuric acid[1] (100% basis) produced in the United States

(Short tons)

Year	Copper plants[2]	Lead and zinc plants[3]	Total
1968	483,108	989,973	1,473,081
1969	685,775	1,086,938	1,772,713
1970	747,784	1,090,817	1,838,601
1971	803,284	971,946	1,775,230
1972	1,010,614	859,103	1,869,717

[1] Includes acid from foreign materials.

[2] Includes acid produced at a lead smelter in 1967–68. Excludes acid made from pyrites concentrates in Arizona, Montana, Tennessee, and Utah.

[3] Excludes acid made from native sulfur.

Table 19.—Secondary copper produced in the United States

(Short tons)

	1968	1969	1970	1971	1972
Copper recovered as unalloyed copper	433,041	514,593	521,137	429,095	447,409
Copper recovered in alloys [1]	785,299	860,900	726,465	771,025	853,564
Total secondary copper	1,218,340	1,375,493	1,247,602	1,200,120	1,300,973
Source:

[1] Brass-mill stocks include home scrap; purchased scrap consumption assumed equal to receipts, so lines in brass-mill and grand total sections do not balance.

[2] Of the totals shown, chemical plants reported the following: Unalloyed copper scrap, 561 tons of new and 2,678 old.

[3] Includes refinery brass.

Table 25.—Consumption of copper and brass materials in the United States by principal consuming group

(Short tons)

Year and item	Primary producers	Brass mills	Wire mills	Foundries, chemical plants, and miscellaneous users	Secondary smelters	Total
1971:						
Copper scrap	516,069	654,140	--	65,952	423,488	1,659,649
Refined copper [1]	--	655,782	1,324,894	31,942	6,889	2,019,507

Total	[r] 6,638,042	6,653,048	7,313,536

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Data presented represent copper content (recoverable where indicated) of ore mined wherever possible. If such data are not available, the nonduplicative total copper content of ores, concentrates, matte, metal and/or other copper bearing products measured at the least stage of processing for which data are available has been used.

[2] Recoverable.

[3] Copper content of concentrate produced.

[4] Corporación Minera de Bolivia (COMIBOL) production plus exports by medium and small mines.

[5] Partly estimated, partly calculated on the basis of data furnished by Companhia Brasiliera de Cobre.

[6] Smelter production.

[7] Includes copper content of cupriferous pyrites.

[8] Excludes an unreported quantity of copper in iron pyrites which may or may not be recovered.

[9] Year ending September 30 of that stated.

[10] Output of Tsumeb Corporation Ltd. and Klein Aub Koper Maatskappy Beperk for years ending June 30 of that stated.

[11] Content of matte produced.

[12] Exports.

[13] Year beginning March 21 of that stated.

Total	6,751,531	6,739,404	7,300,429

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Unless otherwise noted, data presented for each country represent the nonduplicative sum of production of primary blister copper, primary refined copper of nonblister origin, and any primary refined copper derived from unreported quantities of domestically smelted blister copper.

[2] Copper content of impure bars and electrolytic copper.

[3] Smelter output from domestic and foreign ores, exclusive of that produced from scrap. Production from domestic ores only was as follows: 1970—1,605,265; 1971—1,470,815; and 1972—1,649,130.

[4] Includes secondary copper (production from scrap). Partly estimated, partly calculated on the basis of data furnished by Companhia Brasileira de Cobre.

[5] Data are the nonduplicatve sum of: (1) the copper content of blister copper production for sale as such; (2) the copper content of blister copper produced for refining in Chile at the Ventanas refinery; and (3) the copper content of fire refined and electrolytic copper (including copper obtained by electrowinning) excluding electrolytic output of the Ventanas refinery.

[6] Refined.

[7] Belgium reports a large output of refined copper, but this is produced largely from imported blister; estimate of domestic smelter production is based chiefly on reported imports of ores and concentrates.

[8] Series revised; data presented are output of primary smelter. Data presented in previous editions of this chapter represented output of refined metal including secondary (production from scrap).

[9] Reported Norwegian copper output is derived in part form copper-nickel matte imported from Canada, and reported Canadian smelter production may also include this material. Norwegian smelter output from domestic ores was as follows (approximately) in tons: 1970—6,500; 1971—6,700; and 1972—7,500.

[10] Series revised to exclude secondary copper; data presented in previous editions of this chapter included secondary refined copper.

[11] Year ending September 30 of that stated.

[12] Year ending June 30 of that stated.

[13] Series revised; data presented are output of blister copper (including a relatively small quantity of secondary blister, derived from scrap). Data presented in previous editions of this chapter represented output of refined copper, including a substantial quantity produced from scrap as well as quantities produced from imported blister copper.

[14] Refined including secondary.

Diatomite

By Benjamin Petkof [1]

Domestic diatomite production in 1972 increased 8% in quantity and 9% in value compared with 1971 figures. The United States maintained its status as a major world diatomite producer. Exports of processed diatomite to countries throughout the world increased significantly in quantity and value over those of 1971.

DOMESTIC PRODUCTION

Production increased in the major producing States of California and Nevada, but declined in Arizona and Oregon and remained unchanged in Washington. California retained its place as the largest producing State, followed by Nevada, Washington, Arizona, and Oregon.

During 1972 nine companies, with a total of 11 operations, mined and prepared diatomite for various industrial end uses. This was an increase of one producing company from the number reported in 1971. The bulk of the diatomite produced during the year was supplied by the following companies: Johns-Manville Products Corp., with facilities near Lompoc, Calif.; GREFCO, Inc., with operations near Mina, Nev., and Lompoc, Calif.; Eagle-Picher Industries, Inc., with operations near Sparks and Lovelock, Nev.; and Kenite Corp., Division of Whitco Chemical Corp., with an operation near Quincy, Wash. The remaining producers were: Superior Company near San Manuel, Ariz.; Basalt Rock Co. Inc., near Napa, Calif.; Airox, Inc., near Santa Maria, Calif.; The United Sierra Division, Cyprus Mines Corp. near Fernley, Nev.; and A. M. Matlock near Christmas Valley, Oreg. The Kenite Corp. completed an expansion program at the Quincy, Wash. plant with the addition of a new larger kiln and an air classifier.

A new pattern has appeared in the domestic distribution of diatomite filter aid that partially replaces the bagged shipment of the processed diatomite. A bulk distribution station was established at Rollins Terminals in Norristown, Pa., by the Celite Division of the Johns-Manville Products Corp. Prepared filter aid will be shipped from Lompoc, Calif., to Norristown in bulk pneumatic discharge hopper cars, unloaded into silos, and shipped in bulk truck loads to consumers in the eastern United States.

Johns-Manville Products Corp. also announced the introduction of a system to recover spent diatomite filter aid. The system recovers up to 60% of the filter aid from the filter cake using either a batch or continuous method of operation.

[1] Annual figures are confidential, prior to 1969.

---

[1] Physical scientist, Division of Nonmetallic Minerals.

CONSUMPTION AND USES

All major end uses reported significant increases in consumption. However, the percentage of total consumption for each end use varied only slightly from that of 1971. Filtration, the major end use of prepared diatomite, required almost three-fifths of the total material sold or used by producers in 1972. The remainder was used for industrial fillers, insulation, lightweight aggregates, pozzolans, soil conditioners, and other miscellaneous uses.

Table 2.—Domestic consumption of diatomite, by principal use, in percent of total consumption

Use	1968	1969	1970	1971	1972
Filtration	55	58	58	59	58

Insulation	4	4	4	3	4
Miscellaneous	20	18	19	38	38

W Withheld to avoid disclosing individual company confidential data, included with "Miscellaneous."

PRICES

The weighted average value per ton of diatomite for all end uses in 1972, increased only slightly from that of 1971. Small increases in value per ton were reported for almost all end uses except for the abrasives which declined 10%.

Table 3.—Average annual value per ton of diatomite, by use

Use	1971	1972
Filtration	$72.64	$73.08
Insulation	45.34	47.02
Abrasives	139.04	125.27
Fillers	65.92	69.37
Lightweight aggregate	42.97	43.07
Miscellaneous	37.91	39.01
Weighted average	64.25	65.19

FOREIGN TRADE

Exports of prepared diatomite increased 4% in quantity and 7% in value over that of 1971 after declining since 1969. Major countries of destination for these exports were: Canada 25%; West Germany 11%; Japan 9%; the United Kingdom 8%; Australia 6%; Italy 4%; and Republic of South Africa 3%. The remainder was exported to many other developed and undeveloped countries of the world. The average value of exported material was $85.16 per ton. Imports of crude or processed material totaled 63 tons valued at $9,440. This material was imported from Mexico, Kenya, Canada, the United Kingdom, and West Germany. These imports were probably used to evaluate the diatomite deposits of these countries.

Table 4.—U.S. exports of diatomite

(Thousand short tons and thousand dollars)

Year	Quantity	Value
1970	154	12,363
1971	142	11,752
1972	148	12,603

WORLD REVIEW

Overall world production of diatomite remained relatively unchanged from that of the previous year.

Increasing cost of transportation has tended to inhibit the growth of exports of domestically prepared diatomite during the past few years. This situation has stimulated interest in other deposits throughout the world. As a result of this trend the Johns-Manville Products Corp. has begun operating diatomite deposits at Murat, France, and Elch de la Sierra, Spain.

Iceland continued to produce and export diatomite for use as a high-quality filter aid. About one-third of the material exported is sent to West Germany, with the remainder distributed to countries that are mostly in western Europe.

TECHNOLOGY

A mixture has been developed using diatomite as a mineral carrier and containing a degreasing fluid such as trichlorethylene, tetrachlorethylene, or carbon tetrachloride for removing oil, grease, or fat on road, floor, and water surfaces. The mixture can also include a small quantity of synthetic detergent or other surface active material. Floating oil, when treated with this formulation sinks to the sea bottom causing no apparent effect to fish, birds, and other sea life.[2]

Feldspar, Nepheline Syenite, and Aplite

By J. Robert Wells [1]

Domestic production and consumption of crude feldspar declined slightly in 1972, amounting to 99% of the respective 1971 figures and to 97% of those for the record year 1969. Simultaneous increases in utilization of both domestic aplite and imported nepheline syenite, however, brought the 1972 total U.S. consumption of the three feldspathic materials substantially above the corresponding total for 1971 and even farther above that for 1969. A notable feature of the 1972 feldspar situation was the sharp drop in ground feldspar imports, although again that decrease was more than balanced by increased imports of nepheline syenite.

Until about World War I it was customary to report all feldspar statistics, both crude and ground, in terms of short tons, but at that time it became the practice to record crude feldspar production, imports, and consumption in long tons. It is now felt that any advantages of that system have long been outweighed by the difficulty of direct comparisons and by the multiple opportunities for confusion, and that a return to the earlier practice is justified. Beginning with the present 1972 Minerals Yearbook chapter, all feldspar and nepheline syenite data, without exception will be reported in short tons.

Legislation and Government Programs.—According to provisions of the Tax Reform Act of 1969, which continued in force throughout 1972, the depletion rate allowed on feldspar production (both domestic and foreign operations) was 14%.

---

FELDSPAR

DOMESTIC PRODUCTION

Crude Feldspar.—North Carolina, for many years in first place and without close rival as a feldspar-producing State, scored a fifth consecutive annual increase in tonnage in 1972, reaching a point 12% above the output of 1971 and 48% above that of 5 years ago. North Carolina was followed in descending order of tonnage by California, Connecticut, South Carolina, and Georgia. The other four producing States (Arizona, Colorado, South Dakota, and Wyoming) together contributed 2% of the national totals for tonnage and value.

Leading 1972 producers of feldspar were the Feldspar Corp., from mines in Mitchell County, N. C., Middlesex County, Conn., and Jasper County, Ga.; International Minerals & Chemical Corp., from mines in Mitchell County, N. C., and Mohave County, Ariz. (the latter sold in mid-1972);

and Lawson-United Feldspar and Mineral Co., from mines in Mitchell County, N. C.

In 1972, 73% of the total tonnage of feldspar sold or used by producers was flotation concentrate, 24% was feldspar in feldspar-silica mixtures, and only 3% was hand-cobbed, the lowest such proportion since comparable statistics have been kept. The respective corresponding figures for 1971 were 60%, 34%, and 6%; for 1962 they were 66%, 11%, and 23%. Prior to 1952, hand-cobbed feldspar comprised virtually the entire output.

Ground Feldspar.—Most of the feldspar used in glassmaking is ground no finer than 20 mesh, but feldspar to be used in ceramics and filler applications is usually pulverized to minus 200 mesh or finer. Ten companies, operating 14 plants in eight States, ground feldspar for market in 1972, supplying ground material (total tonnage 3% less than in 1971) for shipment to destinations in at least 25 States and a number of foreign countries. Listed in descending order of output tonnages, North Carolina had six grinding mills, while Connecticut, South Carolina, and Georgia had one each. These were the leaders in ground feldspar production and jointly accounted for 94% of the 1972 total. California with one mill, South Dakota with two, Arizona with one, and Wyoming with one, were the four States making up the remaining 6%. Colorado was the only crude feldspar-producing State in 1972 in which no grinding mill was operated.

CONSUMPTION AND USES

Crude Feldspar.—In 1972 there was, as usual, no significant domestic consumption of feldspar in the raw, unprocessed state in which it was taken from the mine; the majority of users purchased their supplies of the mineral already ground and sized either by the primary producers or by merchant grinders. Some manufacturers of pottery, soaps, and enamels, however, continued their customary practice of acquiring relatively small quantities of crude feldspar for grinding to their preferred specifications in their own mills.

Ground Feldspar.—The 1972 pattern of ground feldspar consumption in the United States was not strikingly different from that of the previous year, but the confidential status of some of the 1971 data precludes a detailed comparison. The 1971 end-use distribution, insofar as it was publishable, showed that 51% of the total was consumed for glassmaking and 49% went for pottery, enamel, and miscellaneous uses, compared with 1972 data showing 50% for glass, 44% for pottery, and 6% for enamel and other uses. These data, compared with the averages recorded in the decade of the 1960's (55% for glass,

30% for pottery, 4% for enamel, and 11% for other purposes), suggest a trend toward relatively greater consumption of feldspar for pottery and less for enamel and the other minor applications. In contrast, the proportion of feldspar consumption alloted to glass manufacture has remained comparatively stable since the early 1950's even though the container-glass industry has grown notably in the interim (shipments of glass containers more than doubled in volume from 1952 to 1972). The relatively static position of glass-grade feldspar in the consumption pattern appears to be a reflection of the progressively increasing utilization of imported nepheline syenite (seven times more tonnage in 1972 than in 1952) at the expense of feldspar, as a feldspathic material for glassmaking.

STOCKS

Comparison of the figures reported for 1972 domestic production and sales of feldspar indicated that industrial stocks of that mineral may have risen by approximately one-half during the year. It was estimated that U.S. producers had 440,000 short tons of mined feldspar on hand (crude, ground, or in process) on December 31, 1972, compared with 288,000 tons on that date in 1971 and 149,000 tons in 1970.

PRICES

Engineering and Mining Journal, December 1972, listed the following prices for feldspar per short ton, f.o.b. mine or mill, carload lots, bulk, depending on grade (substantially unchanged from the respective 1971 quotations):

North Carolina:	
20 mesh, flotation	$12.00
40 mesh, flotation	14.00– 21.00
200 mesh, flotation	21.50– 27.50
Georgia:	
40 mesh, granular	20.00
200 mesh	24.50
325 mesh	25.50
Connecticut:	
20 mesh, granular	15.50
200 mesh	22.50
325 mesh	23.50

Feldspar prices were quoted by Industrial Minerals (London), December 1972, as follows (converted from pounds sterling per long ton to dollars per short ton):

Ceramic grade, powder, 200 mesh, bagged, ex-store	$47– 51
Lump, imported, c.i.f. main European port	23– 28

As of July 3, 1972, International Minerals & Chemical Corp. (Canada), Ltd., increased prices for two classifications of its B-grade nepheline syenite (0.5% Fe_2O_3, used for various industrial purposes), minus 30-mesh material from $8.00 per ton to $8.60 per ton, and 40 DD material from $8.50 per ton to $9.15 per ton, in bulk, f.o.b. Blue Mountain, Ontario. Prices for the firm's low-iron grades (0.07% Fe_2O_3, used in the making of glass and fine ceramics) ranged up to $22.00 per ton.

Ceramic Industry Magazine, January 1973, quoted prices for aplite in the range from $6.30 to $12.40 per ton.

Although the foregoing quotations presumably were indicative of price ranges, it is to be understood that most actual sales of feldspar and feldspathic materials in 1972 were concluded as is customary both in the United States and abroad, at negotiated prices not on public record.

FOREIGN TRADE

In 1972, U.S. exports included 5,275 short tons of material indeterminately classified as feldspar, leucite, nepheline, or nepheline syenite (but presumably all or mostly feldspar) with a total value of $183,649, up 32% and 30% from the respective comparable figures for 1971.

Statistics on U.S. feldspar imports, substantially all from Canada, were first reported in a separate category toward the end of 1922. Thereafter, feldspar imports (with the exception of those in the depression years 1932 and 1933) averaged in the neighborhood of 20,000 short tons per year until 1952, when large-scale domestic production of flotation concentrate feldspar overturned existing market patterns. After 1957, imports of feldspar in all forms held relatively steady around an annual average of 4,500 tons, but fell to 2,509 tons in 1971 and (coinciding with the closure of Canada's only remaining feldspar mine) to 1,132 tons in 1972. Imports of Canadian nepheline syenite (one of feldspar's most effective competitors as a feldspathic material) amounted in 1972 to 11% more quantity and 16% more total value than in 1971, the eleventh in a consecutive series of annual increases, pointing to an obvious rationale for feldspar's reciprocally waning significance as an import item. In 1972, U.S. imports included, besides materials definitely in the feldspathic cate-

Table 5.—U.S. imports for consumption of feldspar

Country	1971		1972	
	Short tons	Value	Short tons	Value
Crude: Canada	134	$19,020	187	$23,105
Ground, crushed or pulverized:				
Canada	2,051	54,858	748	16,940
Japan	1	432	--	--
Mexico	16	288	--	--
Sweden	121	4,230	49	1,742
United Kingdom	186	5,113	148	1,125
Total	2,375	64,921	945	19,807

gory, 4,700 short tons of material valued at $305,227 and classified as "natural mineral fluxes, crushed, ground, or pulverized," at least part of which may have been consigned to uses similar to those served by feldspar.

The tariff schedule in force throughout 1972 provided for a 3½% ad valorem duty on ground feldspar. Imports of crude feldspar and of nepheline syenite, crude or ground, were not subject to duty.

WORLD REVIEW

Significant quantities of feldspar were produced in 1972 in at least 35 countries. Feldspar flotation plants were in essentially full-time operation in the United States, Finland, Mexico, and Norway, while dry grinding of feldspar was reported in the United States, France, Italy, and West Germany. Other countries, including several in the Communist group, also processed the mineral in local facilities for their own domestic industries. Nepheline syenite was produced in Canada, mainly for consumption in the United States, and in Norway for markets in western Europe. The U.S.S.R. probably had substantial production of this material also, but definite information was not published.

Brazil.—Feldspar was produced from pegmatitic deposits in east and southeast Brazil and was used in the major industrial centers, especially São Paulo and Rio de Janeiro, mostly for the manufacture of glass and ceramics. Specific data were not released, but the year's output was estimated to lie somewhere in the range of 70,000 to 80,000 tons.

Canada.—International Minerals & Chemical Corp. (Canada), Ltd., Canada's only feldspar producer in recent years, suspended operations at its Buckingham plant in Quebec, reportedly because of declining demand for that mineral. That same firm is Canada's second-largest producer (after Indusmin, Ltd., a subsidiary of Falconbridge Nickel Mines, Ltd.) of the leading alternative feldspathic material, nepheline syenite.

Germany, West.—Besides being among the world's top two or three feldspar producers, West Germany is also a large importer of feldspathic materials. Imports of feldspar, leucite, and nepheline syenite totaled 90,000 short tons in 1970 and 97,000 short tons in 1971. At Hirschau (Bavaria) in what is now West Germany, a private company was founded in 1895 by the Dorfner brothers for manufacturing stoneware and mining kaolin to use as a raw material. The enterprise has remained in the hands of succeeding generations of the same family for nearly eight decades, although making of stoneware stopped in 1920. Present activities of the company concentrate on the mining, processing, and marketing of water-washed kaolin, ground quartz, quartz sands, and potash feldspar.

India.—Total minehead value of India's 1971 production of feldspar was reported at 336,000 rupees, equivalent to $45,000, compared with 275,000 rupees ($37,000) in 1970. Exports accounted for 31% of the output in 1971 (36% in 1970), but different systems of reporting preclude a direct comparison between value of exports and value of production.

Israel.—One of the announced results of a 5-year scientific survey of the Sinai Peninsula was the discovery of a large feldspar deposit (described as "a whole mountain several kilometers square"). No analysis was mentioned, but quality of the mineral was said to be good. The site of the discovery, "only half an hour's drive from Sharm el-Sheikh," would seem to justify rating the deposit as a potentially valuable resource for the not-distant future.

Italy.—In 1971, last year for which data have been released, Italy exported 30,000 short tons of feldspar, 4% more than in 1970. West Germany and Greece were, as usual, the principal recipients of the exported mineral.

Norway.—Norway customarily exports more than half her feldspar output and a much larger share of her production of nepheline syenite. Feldspar output in 1971 was 165,000 short tons, of which 87,500 short tons (53%) was exported; nepheline syenite production was 176,500 short tons, of which nearly all (98%) was shipped to foreign destinations.

South Africa, Republic of.—In a catalogue of working mines, as of December 31, 1969, 11 mines were listed as producing feldspar. Mica and silica were mentioned as coproducts from a number of those operations. Active feldspar mines were situated in the Namaqualand district (one mine) and the Kenhardt district (two mines) of Cape Province; and the Lataba district (eight mines) of Transvaal Province. About 70% of the 1970 feldspar production was exported (14,500 out of 20,800 short tons), while in 1971 exports slightly exceeded the year's mine output (13,500 short tons produced, 13,600 short tons exported).

United Kingdom.—Charter Exploration, Ltd., a London-based mining firm, announced plans to undertake the mining

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] In addition to the countries listed, Brazil, People's Republic of China, Czechoslovakia, Romania and Territory of South-West Africa produce feldspar, but available information is inadequate to make reliable estimates of output.

[2] Described in source as lump feldspar; does not include nepheline syenite as follows, in short tons: 1970—162,088; 1971—176,470; 1972—[e] 176,000.

[3] Includes pegmatite.

[4] Data are for years ending June 30 of that stated.

[5] In addition the following quantities of aplite and saba were produced: aplite: 1970—514,508; 1971—448,162; 1972—501,648; saba: 1970—10,748; 1971—6,005; 1972—1,336.

and processing of feldspar from a newly discovered deposit, near Durness in Scotland's Sutherland County. The deposit contains at least 2 million tons of recoverable mineral of industrial quality. It was anticipated that expenditure of $1.2–$1.7 million would be sufficient to set up facilities to initiate operations at the rate of 50,000 tons per year. At present, all feldspar consumed in the United Kingdom is obtained by importation, mostly from Finland, Norway, and Yugoslavia.

A symposium, designated as the Advanced Study Institute on Feldspars, was held at the University of Manchester in July 1972. Membership of the Institute, which was sponsored by NATO, consisted of lecturers and students, many of whom presented research papers dealing with specific aspects of the study of feldspars and related disciplines. Publication of the Institute's act was expected in late 1972 or early 1973.

TECHNOLOGY

Magazine articles were published that outlined the mining, milling, and flotation procedures being used by a West German firm in the production of a number of ceramic raw materials including 18,000 tons per year of glass-grade feldspar,[2] and by a company in Finland that has an annual output of 70,000 tons of feldspar concentrate and 30,000 tons of quartz concentrate for the making of glass and ceramics.[3]

The technological aspects of the selection, quality control, and preparation of ceramic materials, including feldspar, and of their fabrication into special-purpose insulators were some of the subjects dealt with in a journal article.[4] Feldspar was one of the raw materials mentioned in a magazine article as an ingredient in body formulations for efficient production of ceramic tile.[5] Important advances in whiteware firing technology were discussed in an industrial journal. It was stated that, for best results, the fluxes used have to be specially selected. Economy of soaking time at maximum temperature, for example, was achieved by the use of nepheline syenite in lieu of feldspar in the body mixtures.[6]

Although porcelain enameling on metal has been a feature of a number of human cultures for at least twenty centuries, no end is yet in sight for advances in this ancient art. Feldspar in varying proportions enters into most enamel formulas, and the permutations of those variations with the large number of other compositional possibilities permits the compounding of literally thousands of different types of enamel frits suitable for a range of applications extending from multicolored jewelry for personal adornment to large expanses of weather-resistant paneling for major buildings. How well porcelain enameling is keeping pace with today's metallurgical and structural progress was the subject of a journal article.[7]

The one most important outlet for feldspathic materials is in the manufacture of glass bottles and jars to contain beverages, foods, and pharmaceutical products. A substantial majority of such containers, for reasons of convenience and even of actual economy, are discarded after a single use. Salvaged glass, crushed to sand size and amounting to 5 percent of the furnace charge, was mixed with customary raw materials at a Pennsylvania glass works and melted down in a 24-hour, commercial-scale test to produce 3½ thousand gross of new beverage bottles. The waste glass for this successful test, of which the environmental and conservational implications are obvious, was recovered from city incinerator residues by a process and in a pilot plant both developed by the Bureau of Mines. As another part of its continuing research program in quest of advantageous outlets for scrap glass, the Bureau of Mines issued a report concerning experimental production of glass wool from the glass fractions of urban solid waste.[8]

A booklet[9] published by an association of concerned industrialists presented a chalk-talk discussion of the contribution of container glass to the urban refuse situation and outlined some of the association's activities that are being devoted to efforts to defuse that component of the problem. Toward that end, the organization has undertaken a program to investigate the possibilities, technologies, and economic involvements of the salvaging and reutilization of waste container glass in potentially profitable enterprises. Goals of this research include the development of economical processes for mechanically separating glass from other solid wastes, for using the maximum amount of the material so recovered in the making of new glass containers, and for channeling the rest into commercially viable applications.

A number of articles appeared in industrial journals that dealt with the current status of glass recycling technology.[10] Possible applications for the reclaimed material were discussed that, in addition to the reworking into new containers, included use in the production of road-surfacing aggregates, building blocks, bricks, structural panels, terrazzo tiles for flooring, sewer and drain pipes, insulating materials, and decorative or light-reflecting paints. Also mentioned were several smaller scale uses ranging from costume jewelry to poultry grit.

NEPHELINE SYENITE

Nepheline syenite is a feldspathic igneous rock with a texture similar to that of granite that is extensively used in place of feldspar as an alumina-bearing raw material for glassmaking and in the whitewares industry both as a body component and in frits for glazing. In a relatively recent development, increasing quantities of nepheline syenite are being ground to extreme fineness for use as a filler in plastics, foam latex products, paper, and paint. Nepheline syenite mined in the United States (Arkansas) is used only as stone (mostly for roofing granules or road metal); all nepheline syenite consumed here for glass and ceramics is imported from Canada, the world's foremost producer. Canada's 1972 shipments of nepheline syenite (all from two operations at Blue Mountain, Ontario) were estimated at 560,000 short tons, valued at $7.07 million. The average unit values reported for Canadian production and U.S. imports of ground nepheline syenite in 1972 were $12.62 and $12.45 per short ton, respectively, or about 5% more than the comparable figures for 1971. The world's second-largest producer of glass- and ceramic-grade nepheline syenite is Norway; shipments from that source in 1971 amounted to 165,000 short tons. The U.S.S.R. also mines nepheline syenite on a commercial scale, but reportedly the output is used only for production of metallurgical-grade alumina.

Table 7.—U.S. imports for consumption of nepheline syenite

Year	Crude		Ground	
	Short tons	Value (thousands)	Short tons	Value (thousands)
1970	603	$2	395,289	$4,634
1971	636	12	413,862	4,912
1972	3,027	43	456,406	5,681

APLITE

Aplite is a granitic rock with a high proportion of albite (soda feldspar) or plagioclase (lime-soda feldspar), either of which makes it potentially useful as a raw material for the manufacture of container glass. To become acceptable for that purpose, however, the mined material usually must first be processed to eliminate all but a trace of the iron-bearing minerals it contains. Aplite of glassmaking quality was produced in the United States in 1972 from two open pit mines in central Virginia. The Feldspar Corp. mined aplite ore near Montpelier, Hanover County, and removed iron from it by an electrostatic process. International Minerals & Chemical

Corp. operated a mine near Piney River, Nelson County, and subjected the crude aplite to a high-intensity treatment to separate iron minerals. Aplite mine production in 1972 continued the upward trend of recent years and was 6% greater in tonnage than in 1971, although the reported total value was sharply lower. Specific annual data on aplite production, sales, and value have not been released for publication since 1962. That year's output was 140,000 short tons, valued at $0.9 million.

Ferroalloys

By Norman A. Matthews[1]

The overall structure of the domestic ferroalloy industry did not change basically during 1972. Management elected to close some older plants rather than invest heavily in the pollution control equipment necessary to meet the stringent emission requirements projected for 1976. The volume of business improved at yearend as the principal consumers of ferroalloys, the steel, cast iron, and aluminum industries, approached capacity operations. However ferroalloy imports increased to such a degree that total domestic shipments remained practically unchanged compared to those of 1971. Exports of ferroalloys continued to decline with the total volume reduced 43,000 tons (49%), whereas value declined only $3 million as the export product mix changed considerably. Published prices were generally constant during the year but did not govern in many of the major commodities as domestic producers acted to counter prices of imported products.

Detailed information concerning utilization of individual elements in various alloy products may be found in the chromium, manganese, silicon, molybdenum, nickel, tungsten, and vanadium chapters.

---

[1] Includes briquets and fused-salt electrolytic.
[2] Includes silicon metal and inoculant type alloys.
[3] Includes chromium briquets, chromium metal, exothermic chromium additives, and other miscellaneous chromium alloys.
[4] Includes ferroboron, and other complex boron additive alloys, ferronickel, ferromolybdenum, ferrotungsten, ferrovanadium, spiegeleisen, ferrozirconium, and other miscellaneous alloys.

DOMESTIC PRODUCTION

The number of ferroalloy producers declined from 29 to 25 at yearend 1972. Agrico Chemical Co. closed its phosphorus and ferrophosphorus facility at Pierce, Fla., in August, and Hanna Furnace Corp., Division of National Steel Corp., Buffalo, N.Y., stopped producing silvery pig iron at yearend. The Ohio Ferro-Alloys Corp. plant at Tacoma, Wash., was closed late in the year and Foote Mineral Co. announced that it would close its plant at Steubenville, Ohio, in 1973. N L Industries, Inc. ceased production of specialty ferroalloys at its Niagara Falls, N.Y., plant at yearend as the facilities were converted to processing other commodities.

Alabama Metallurgical Corp., which produced ferrosilicon at Selma, Ala., merged with the Globe Metallurgical Division of Interlake Corp. and continued to operate as a part of the division.

Although production of wrought steel and iron castings increased 11% in 1972 compared with that of 1971, total domestic ferroalloy shipments did not change significantly, principally because of the increased volume of imported ferroalloys that went into the domestic market.

Union Carbide Corp's. Ferroalloys Division is installing a $7.6 million computer-controlled 45 MW ferrosilicon furnace at Astabula, Ohio, for completion in 1975. Projected capacity is 75,000 tons per year of 50% ferrosilicon. Otherwise the domestic industry is investing, at a maximum rate consonant with earnings, in pollution control equipment to meet the emission requirements projected for 1976.

Table 3.—Producers of ferroalloys in the United States in 1972

Producer	Plant location	Product [1]	Type of furnace
Agrico Chemical Co	Pierce, Fla	FeP	Electric.

U.S. Steel Corp	Clairton, Pa McKeesport, Pa	FeMn	Blast.
Woodward Iron Co	Woodward, Ala Rockwood, Tenn	FeSi, FeMn, SiMn	Electric.

[1] CrMo, Chromium molybdenum; FeMn, ferromanganese; Spln, spiegeleisen; SiMn, silicomanganese; FeSi, ferrosilicon; FeP, ferrophosphorus; FeCr, ferrochromium; FeMo, ferromolybdenum; FeNi, ferronickel; FeTi, ferrotitanium; FeW, ferrotungsten; FeV, ferrovanadium; FeB, ferroboron; FeCb, ferrocolumbium; NiCb, nickel columbium; Si, silicon metal.

[2] Includes Alsifer, Simanal, zirconium alloys, ferrosilicon boron, aluminum silicon alloys, and miscellaneous ferroalloys.

CONSUMPTION AND USES

Consumption of the ferroalloys during melting, refining, and finishing of heats of steel increased proportionately to steel production in 1972, showing an 11% increase compared with that of 1971. Overall growth of additive alloys consumption for all uses was 13%, with a marked increase in silicon usage in the production of steel and cast iron.

Consumption of the ferroalloys as alloying elements increased 31% in 1972 compared with that of 1971, representing principally growth in the use of chromium and nickel in the production of stainless and alloy steels. Ferronickel is listed in the consumption table (table 5) for the first time, since the use of this form of nickel has increased substantially.

The consumption data for alloying elements listed in table 5 understates total consumption of several elements in most instances since it covers only the ferroalloy forms. Alloying elements such as nickel, molybdenum, tungsten, and vanadium may be added to metallic melts in any one of several forms. The practice varies as relative economics change and technological progress permits greater latitude in the choice of form of the alloying addition.

The following tabulation gives the proportion of the above alloying elements added in the ferroalloy state in relation to other product forms. It refers only to metallic products, neglecting chemicals and other end uses.

Element	Added as ferroalloy [1] (%)	Added in other forms (%)
Molybdenum	25	75
Nickel	19	81
Tungsten	16	84
Vanadium	92	8

[1] Modified as in notes to table 5.

For a more complete analysis of the consumption patterns, the reader is referred to the respective commodity chapters.

[3] Includes calcium molybdate but not molybdenum oxide.
[4] Includes melting base self-reducing tungsten.
[5] Includes other vanadium-carbon-iron ferroalloys.

STOCKS

Producers' stocks increased substantially at yearend compared with those at the end of 1971, with 80% of the increase in manganese alloys. There were also modest increases in chromium and phosphorus alloy stocks and a sizable percentage increase in ferrovanadium producer stocks.

Consumer stocks increased logically in relation to the volume of business for most commodities, showing a modest percentage increase for the large-volume commodities and a substantial percentage increase for ferronickel and ferromolybdenum.

Table 6.—Stocks of ferroalloys held by producers and consumers in the United States, December 31, 1972

(Short tons)

	Producer		Consumer	
	1971, gross weight	1972, gross weight	1971, gross weight	1972, gross weight

W Withheld to avoid disclosing individual company confidential data.
[1] Includes ferromanganese, siliconmanganese, spiegeleisen, and manganese metals.
[2] Includes ferrosilicon, silvery iron, silicon metal, and miscellaneous silicon alloys.
[3] Includes other chromium ferroalloys and chromium metal.
[4] Includes other titanium materials.
[5] Includes other phosphorus materials.
[6] Includes calcium molybdate.
[7] Includes melting base self-reducing tungsten.

PRICES

Published ferroalloy prices on the major items remained essentially constant during the year 1972 but such prices did not apply in many cases as domestic producers adjusted prices to compete more effectively with imports. Published prices on the major chromium-containing alloys were withdrawn by major producers in October and not quoted throughout the remainder of the year. The prices quoted for manganese, silicon, molybdenum, tungsten, columbium, and titanium-containing alloys were not changed significantly as imports exerted increasing downward pressure on prices in a finite market. Prices quoted for some vanadium alloys were increased 2% and 5% in July 1972, and the price quoted for ferronickel was increased 7% in December.

FOREIGN TRADE

The decrease in volume of U.S. exports continued as the number of competing countries with exportable surpluses increased. The most pronounced decreases were in ferrosilicon, ferrophosphorus, and ferrovanadium. There were substantial increases in the volume of ferromanganese and ferrochromium exports. The total dollar value of exports declined from $23 million in 1971 to $20 million in 1972.

In contrast, the volume of imports increased substantially overall and most markedly in the major commodities, ferrochromium, ferromanganese, and ferrosilicon, involving respective increases of 66%, 44%, and 57%. The volume of ferronickel imports doubled as the total volume and value of imports in 1972 increased 56% and 66%, respectively, compared with those of 1971.

WORLD REVIEW

Table 9 lists ferroalloy production in the world by country and furnace type for the years 1970 through 1972 from the most reliable data sources. Production increased moderately overall in 1972 compared to that of 1971 and 1970 as steel production increased rapidly to near-capacity levels late in the year. There were exceptions, such as Japan, where excessive inventories had accumulated during the first half of 1972.

The stagnation that occurred recently in the steel industry of the free world started earlier in the United States and spread rapidly throughout the free world. Underutilization of steel facilities implies an excess of ferroalloy capacity in those countries with established ferroalloy industries. Such conditions promote more international flow of those ferroalloy commodities in surplus with increasing exports to markets commanding higher prices such as the United States. As a result increasingly higher quantities of ferroalloys were imported into the United States during the interval 1970–72.

Belgium.—S.A. Application de la Chimie, de l'Electricité et des Métaux (SADACEM) completed installation of a 20 MVA enclosed ferroalloy furnace in 1972. This furnace, and a similar one installed in 1971, will be used principally to produce manganese alloys more efficiently and with proper control of emissions to the atmosphere.

Bolivia.—Empresa Nacional de Fundiciones (ENAF) engaged Skoda Export to conduct a feasibility study on a proposed ferroalloys plant near Lake Titicaca to produce 500 and 300 tons of ferrotungsten and ferrovanadium, respectively, per annum for the Andean Pact nations. Tungsten raw materials would be provided from tin operations in Bolivia whereas vanadium minerals would be imported.

Brazil.—Cia. de Ferro Ligas da Bahia, S.A. (the FERBASA group) has installed capacity to increase ferrochromium production from 12,000 tons in 1972 to an estimated 45,000 tons in 1973. Most of the additional output will be exported. Proven ore reserves do not justify further additional expansion but intense exploration was proceeding in adjoining promising geological formations.

Sibra Electro Siderúrgia in Bahia has contracted with Nippon Kokan KK to construct a $2.5 million ferroalloy facility in Brazil involving a 23 MVA furnace for high carbon ferromanganese and a 21 MVA furnace for silicon manganese. The anticipated output of 100,000 tons per year by 1975 is destined for export principally.

South Africa, Republic of.—The South African ferroalloys industry is engaged in major expansion programs aimed principally at the export market. African Metals Corporation (AMCOR) through its manganese subsidiary Metalloys Ltd. at Kookfontein, Transvaal, is installing two 42 MVA furnaces, both of which are to be in operation by the end of 1973. Overall the goal of AMCOR is to increase exports of high- and medium-carbon ferromanganese, ferrosilicon and high-carbon ferrochromium from 100,000 to 300,000 tons per year by 1974.[2]

The Ferrometals Ltd. division of African Metals Corporation at Witbank has completed a 35 MVA silicon furnace with an estimated capacity of 50,000 tons per year with the expectation that its production will be principally for export. A second furnace of 48 MVA devoted to high-carbon ferrochromium with an annual capacity of 125,000 tons, of which 80% will be available for export, is planned for completion in 1973.

Because of the increased adoption of post-melting furnace treatments, higher percentages of the lower cost high-carbon ferrochromium types can be utilized in producing stainless alloys. Through beneficiation the lower grade Transvaal ores can be smelted directly and compete for a major percentage of the ferrochromium business.

African Oxygen (subsidiary of British Oxygen), Aluminum Company of Canada, and Foote Mineral Co. have formed Silicon Smelters Pty. Ltd. to construct a silicon metal electric furnace reduction plant of 30,000-ton-per-year capacity at Pietersburg in the Transvaal. Most of the product will be marketed for the alloying of aluminum. Delta Manganese Pty. is constructing a $21 million electrolytic manganese facility in the Transvaal with initial production in

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, the People's Republic of China and North Korea are known to produce ferroalloys but output of these materials are included in estimates for pig iron in the iron and steel chapter, therefore they have been omitted here to avoid duplication. East Germany also is known to produce ferroalloys but it is not clear from source publications whether output has been included together with that of pig iron in the iron and steel chapter. Also, Colombia, Greece, Norway, Peru, Venezuela, and Southern Rhodesia may produce ferroalloys and output, if any, is also included with pig iron in the iron and steel chapter.

[2] Blast furnace ferroalloy production by Australia, Canada, and United States included under electric furnace output; that of Czechoslovakia is included under pig iron.

[3] Blast furnace ferromanganese and spiegeleisen only; other blast furnace ferroalloys are included with pig iron production in the iron and steel chapter.

[4] Revised to include blast furnace ferrosilicon previously reported with pig iron.

[5] Includes electric furnace ferroalloys if any are produced.

[6] In addition to the countries listed, the United Kingdom and the U.S.S.R. are known to have produced electric furnace ferroalloys and Romania may have produced some electric furnace ferroalloys, but output is not reported and no basis for estimation is available.

[7] Year ended November 30 of year stated.

1974 and capacity operation of 28,000 annual tons in 1975. Foote Mineral Co. will be the exclusive sales agent in the United States and Mexico.

Transvaal Alloys has initiated development of a 4,000-ton-per-day mine and concentrator to exploit the Busveld Development vanadium deposit near Uitvlugt in the Transvaal. Production of 1,500 tons per year of vanadium pentoxide is planned at a plant site at Staffberg with initial shipments in 1974.

Highveld Steel and Vanadium Corp. at Witbank is expanding steel and iron-smelting capacity by 25% and thereby increasing its vanadium slag output proportionately. The additional slag production will be for export.

Spain.—Hydro Nitro Española brought into production in May 1972 a 45 MW refined ferromanganese furnace at Huesca. A second furnace was started up by yearend. Annual export of 30,000 tons of ferromanganese was projected until new steel capacity in Spain is brought onstream in 1975–76.

United Kingdom.—British Steel Corp. completed a $6 million modernization program on the No. 5 blast furnace at the South Teeside Works which, with the adjoining No. 4 blast furnace, provides capacity of 200,000 tons per year of ferromanganese. The combined facility is capable of supplying the total high-carbon ferromanganese requirements projected for the United Kingdom steel industry in the foreseeable future.

TECHNOLOGY

The secondary refining or post-furnace treatment techniques involving oxygen-argon or oxygen injection in separate closed vessels (A.O.D. or V.O.D. processes) have been adopted rapidly by many of the larger stainless steel melting shops in the United States, Japan, and Western Europe. The processes permit higher production rates from melting furnaces and greater percentage utilization of high-carbon ferrochromium, effecting savings estimated conservatively of $20 per ton.

Foundries producing ductile iron are anxious to reduce smoke and fume from the ladle reactions associated with magnesium additions. To meet this need, International Nickel Co., Inc., introduced two alloys, INCOMAG 3 and 4, with controlled density and 4% to 5% magnesium which reduce smoke appreciably, and Ferroalloys Division of Union Carbide Corp. introduced REMAG, a cerium-magnesium-45% silicon alloy which reduces smoke similarly.

Calcium, in conjunction with aluminum and silicon, in the deoxidation of gear steels results in lower hardness inclusions than aluminum-silicon deoxidation. Complex calcium-aluminate inclusions form instead of the extremely hard alumina inclusions; the result is considerable improvement in cutting edge life of the tool steel cutters utilized in machining automotive gears and pinions. Improvements in number of pieces produced per rougher tool grind have ranged from 60% to 100% in applications on subsequently heat-treated high-performance carbon and alloy steel parts.

Fluorspar and Cryolite

By H. B. Wood[1]

FLUORSPAR

World supply of fluorspar improved greatly during 1972. At yearend U.S. consumers found no shortage of either acid-grade (acid-spar) or metallurgical-grade (met-spar) fluorspar. In fact, additional supplies were readily available from Mexico and the Republic of South Africa.

Although prices in 1972 reached an all-time high, some new 1973 contracts showed lower prices. However, no significant reduction in price is anticipated in the near future. Devaluation of the dollar and adjustments in foreign exchange rates also tended to cause higher prices.

During the last 3 to 4 years, accelerated exploration has been inspired by rising prices. As a result many new discoveries or mine expansions were made in Mexico, Thailand, the Republic of South Africa, and even in the United States. New fluorspar deposits started to come into production by yearend.

Overall consumption of fluorspar in the United States showed little change compared with 1971. In 1972 the United States consumed 1,352,000 short tons or about 26% of the estimated world supply while only producing 250,000 tons or about 5% of the estimated world supply. In other words, only 18% of U.S. consumption was indigenously produced. Demand for fluorspar in the steel, chemical, and aluminum industries continued strong. Combined, these industries consumed over 90% of the U.S. total. The rest was consumed by the ceramic, glass, cement, nuclear reactor, and oil industries. Notable growth in consumption is anticipated in the uranium industry to produce uranium tetrafluoride, and in the oil industry as a catalyst. Less acid-spar was used by aluminum companies which recycled more waste fluoride compounds. In addition, fluorine from fluosilicic acid (H_2SiF_6), a byproduct recovered during phosphoric acid manufacture, was processed to make cryolite and aluminum fluoride for use in primary aluminum production. In 1972 this new supply was equivalent to the amount of fluorine obtainable from about 55,000 tons of acid-spar.

Legislation and Government Programs.—As of December 31, 1972, Government stockpiles included 921,826 tons of acid-spar, with 350,000 tons of acid-spar credited as 438,000 tons of met-spar towards the met-spar objective. Government stockpiles also included 411,788 tons of met-spar. The percentage depletion allowance rates established in 1969 remained the same; domestic 22% and foreign 14%.

The Office of Minerals Exploration, U.S. Geological Survey, in September 1972 executed a fluorspar exploration contract with Hicks Dome Account of New York City. Exploration started in 1972 on the Hicks Dome prospect in Hardin County, Ill.

During 1972 no action was taken on Congressional Bills H.R. 11696, H.R. 11735, H.R. 11767, and H.R. 11976, which in 1971 had been introduced into the U.S. Congress to suspend the current import duty on fluorspar until January 1, 1974.

DOMESTIC PRODUCTION

Total U.S. production of fluorspar decreased 8% from 272,000 tons in 1971 to 250,000 tons in 1972. A softening in the demand for acid-grade fluorspar during the second half of 1972 probably caused the closing down of Minerva Oil Co.'s old Crystal Mill at Cave-In-Rock, Ill., and the reduced production from the Calvert City Chemical Co.'s plant near Mexico, Ky.

The Illinois fluorspar mining district, consisting of Hardin and Pope Counties in southern Illinois, continued as the principal source of domestic fluorspar in 1972 and provided 53% of total U.S. shipments for the year. The lead and zinc byproducts of the Illinois fluorspar mines were also important to the operations. Other producing States were Colorado, Montana, Nevada, Texas, Utah, Arizona, New Mexico, and Kentucky where byproducts were not significant. By producing at about the same rate as a year earlier, Colorado maintained its position as the second largest fluorspar-producing State in the United States.

---

[1] Geologist, Division of Nonmetallic Minerals.

In 1972, the mining industry operated at normal levels. The acid-spar market softened in the last quarter, but the metspar-market remained strong. New mines opened in Illinois, Texas, and Arizona, but no shipments were reported from two mines in Arizona, three mines in Utah, or from one mine each in Nevada, Idaho, and Kentucky. In 1972, 12 companies operated 24 mines in Arizona, Colorado, Illinois, Kentucky, Montana, New Mexico, Nevada, Texas, and Utah. Fluorspar ores were concentrated in 15 heavy-media and/or flotation plants. Employment totaled approximately 1,200 men. Fluorspar shipments were valued at over $17 million.

[2] Data may not add to totals shown because of independent rounding.

In Alaska, Lost River Mining Co. Ltd. continued feasibility studies and some metallurgical research. However, there were no indications that mine and surface operations had gotten underway.

In Arizona, Tonto Mining and Milling Co., Inc. with operations northeast of Phoenix, continued working three small mines and a flotation plant, which has a reported annual capacity of 30,000 tons of acid-spar. The acid-spar product was shipped to Allied Chemical Co.'s HF plant at Pittsburgh, Calif.

In Colorado, the Ozark-Mahoning Co. in the Northgate district, and the Allied Chemical Co. at Jamestown, continued to be the principal producers of fluorspar ore.

In Idaho, N.L. Industries Inc. staked mill-site claims and performed exploratory drilling and drifting to develop the Bayhorse fluorspar prospect located southwest of Challis. A major effort was expended in mapping the area and gathering information for an environmental impact study. Seaforth Minerals and Ore Co. carried out more extensive drilling to learn if there was enough minable ore to justify building a froth flotation plant near its Meyers Cove fluorspar deposit. Ozark-Mahoning performed exploration drilling on its Chalspar group of unpatented claims on Garden Creek west of Challis.

In Illinois, Ozark-Mahoning and Minerva Oil Co. were operating at near full capacity. Ozark-Mahoning started its Knight mine shaft, produced regularly from the NEL Davis Nos. 4 and 7 shafts and from the North Green and Bonnet mines, and operated the Rosiclare mill around the clock. At the Minerva No. 1 flotation plant near Cave-in-Rock, Minerva Oil Co. processed ore from mines in Illinois and Kentucky. In October Minerva closed down the froth flotation circuit at its Crystal Mill in Illinois, and thereafter intermittently operated only the heavy-media circuit.

In Kentucky, Cerro Corp. as the operator for the joint venture of Cerro and three associates started sinking a shaft on the Babb-Barnes tract near Mexico. It is reported that this shaft and the related flotation plant will be completed near the close of 1973. Calvert City Chemical Co. operated a modernized flotation plant in Mexico, on ores from the Shouse and Babb-Guill mines.

In Montana, Roberts Mining Co. continued to ship from stockpiles of gravel met-spar at Darby. Management reported that production has not been resumed at the open pit mine because of Montana's environmental regulations.

In New Mexico, Midwest Oil Co. and Perry-Knox and Kaufman Inc. obtained leases on the Turtle Dove claims within the E. T. Chavez Ranch near Truth-or-Consequences. An extensive exploration program was started late in 1972. The mine and small flotation plant of Win Industries, west of Truth-or-Consequences, went on-stream the first part of 1972. However, soon after opening a flash flood washed out the road and part of the stockpiled fluorspar; operations were never resumed during 1972.

In Oregon during the fall of 1972, Aluminum Company of America (Alcoa) acknowledged that a large number of claims had been staked on a fluorspar prospect in the Crooked River area 5 miles west of Rome, Oreg. This prospect was described in a U.S. Geological Survey publication.[2] Fluorspar assays up to 20% CaF_2 were reported, but the average is about 8% CaF_2. A resource of 12 million tons was estimated in the report. Alcoa personnel do not consider this occurrence to represent an economically viable deposit, because of metallurgical and processing problems, but more exploration and research will be done. To date, no known laboratory tests have been successful in extracting the micron-size fluorspar grains from the matrix of zeolites and silicates disseminated in fine-grained zeolite tuffaceous siltstone.

In Tennessee, Amoco Minerals Co. completed drilling 26 holes in 1972 on a fluorspar prospect in the Sweetwater barite district. A breccia zone containing a reported 10 million tons of 15% CaF_2 was drilled out. No additional activity has been reported at this paramarginal deposit, ever since Amoco completed its exploration program.

In Texas, D. & F. Minerals Co. mined fluorspar from the La Mina Paisano mine in the Christmas Mountains, and shipped met-spar to Delhi Foundry Sand Co's buying station at Marathon for transhipment to Kaiser Steel Co.'s steel smelter at Fontana, Calif.

In Utah, only the Wilden Fluorspar Co. shipped some met-spar. Three previously active mines owned by other companies did not produce.

The manufacture of fluorspar briquets or pellets continued at the six known plants in the United States. Fluorspar concentrates of near acid-spar grade were used by Ozark-Mahoning, Cometco Corp., and Mercier Corp. to make briquets of variable CaF_2 content. The plants at Brownsville, Tex., reportedly used flotation concentrates and high-grade fines from met-spar washing plants.

CONSUMPTION AND USES

Fluorspar containing different percentages of CaF_2 is essential to the steel, glass, ceramic, and cement industries. Fluorine, as hydrofluoric acid (HF), is essential to the chemical, aluminum, oil, and nuclear reactor industries. The consumption trends of fluorspar depend directly on the growth of the previously mentioned industries. Within the United States, the steel industry consumed about 43% of the total fluorspar, the chemical industry about 36%, the aluminum industry about 14%, and other industries about 7%.

Table 5.—U.S. consumption of fluorspar by end use and by grade in 1972

(Short tons)

End use or product	Containing more than 97% calcium fluoride	Containing not more than 97% calcium fluoride	Total
Hydrofluoric acid	717,785	(1)	717,785

Total	1,352,149

[1] Includes Florida, Georgia, Maryland, North Carolina, Virginia, Delaware, Mississippi, and Oklahoma

Fluorspar consumption by the steel industry is basically affected by business fluctuations and changes in fluorspar requirements per ton of steel. World steel production rose approximately 8% from 1971 to 1972, and U.S. production rose approximately 10%. Consumption of fluorspar as a steel flux increased about 2.7%, whereas consumption of other fluxes, exclusive of limestone and fluorspar mixes, increased about 37%. However, the use of substitute fluxes has not been widely accepted by steel producers. Consumption of fluorspar per ton of steel dropped from about 9 pounds in 1971 to about 8 pounds in 1972. This reduced consumption per ton was probably caused to some extent by use of substitutes, but mostly to more efficient use of fluorspar.

Quality met-spar is needed when smelting high-carbon steel. Other fluxes such as red mud, manganese slag, olivinite, ilmenite, lime-iron oxide mixes, and colemanite have been tested in combination with met-spar or as a complete substitute for use in fluxing a select group of low-carbon steels. Generally, these substitute fluxes were slower reacting, required more pounds per ton of steel, were not as effective purifiers, and were not available in sufficient quantity or at reasonable prices.

Although long-term demand for steel in the United States is anticipated to grow at a rate of 2.5% annually, steel production in 1973 may reach 145 million tons, a 9% increase over that of 1972. For 1972, the American Iron and Steel Institute (AISI) reported that about 531,000 tons of fluorspar was used; this compares with 588,000 tons shown in table 5, which is the figure compiled from Federal Bureau of Mines canvasses. If the 1973 steel production estimate of 145 million tons is achieved and the U.S. consumption of fluorspar continues at the rate of 8 pounds per ton, consumption will be about the same as in 1972.

The fluorspar consumption rate by U.S. Steel's "Q-BOP" (basic oxygen furnace) process has not been reported publicly, and cannot be accurately determined until a new plant is brought into production. In the "Q-BOP" operation, finely-ground fluorspar, along with powdered lime, is blown in from the bottom, and scrubbing devices are installed to recover any discharge gases and particulates. Reportedly, the "Q-BOP" smelter is designed to replace open-hearth furnaces as they are phased out.

Most of the acid-grade fluorspar containing more than 97% CaF_2 is used to make HF or hydrogen fluoride (table 5). HF has many uses. In the chemical industry many inorganic and organic compounds are made from HF, such as aluminum fluoride, cryolite, sodium fluosilicate, potassium fluosilicate, sodium fluoride, ammonium fluoride, and a long list of fluorocarbons. It is also commonly used in glass etching, stainless steel pickling, petroleum alkylation, in making uranium tetrafluoride, and in water fluoridation. Inorganic fluorides are used mostly as electrolyte fluxes in the production of aluminum. Fluorocarbons are used commonly as refrigerants, aerosol propellants, plastics, and foam applicators.

World production of HF is increasing. West European countries have the largest number of HF plants in operation in the free world. In addition, there are two working plants in Canada; three in Mexico, with another being built at Matamoros, Tamaulipas, Mexico; two in Japan, with another being built; and one in Australia (still in process of being built).

U.S. consumption of HF has been estimated by W. R. Jones of E. I. du Pont de Nemours & Co. Inc. at 365,000 tons in 1972 and 500,000 tons by 1977. In explaining U.S. demand, Mr. Jones stated, "The fluorocarbon and aluminum industries consumed 80% of the HF now produced in the U.S. and major HF growth will continue in those industries. Use in petroleum alkylation and uranium processing will grow the fastest in the remainder of the 70's, but still represent less than 10% of the total HF consumption for the foreseeable future. Overall a 6.5% growth rate is projected for HF over the next 5 years."[3]

Consumption of HF (70% aqueous) in 1972

End use	Quantity (short tons)	% of total
Fluorocarbons	145,000	40
Aluminum	145,000	40
Petroleum alkylation	15,000	4
Uranium	7,500	2
Stainless steel pickling	12,500	3
Fluoride salts	12,500	3
Miscellaneous	27,500	8
Total	365,000	100

Oversupply of fluorocarbons was expected to persist until 1976 owing to overcapacity construction of fluorocarbon plants, and to substitution of cheaper hydrocarbon propellants. According to H. Lee Noble of Allied Chemical Corp., 1972 U.S. fluorocarbon demand was about 420,000 tons and capacity was 610,000 tons; incremental expansions by 1976 will raise U.S. capacity to 675,000 tons, while anticipated demand will only increase to about 580,000 tons. Sales of fluorocarbons for propellants was anticipated to grow 6% to 7% per year through 1978, and to represent 48% of the fluorocarbon market.

Noble estimated that from 1972 to 1978, the refrigeration and air-conditioning market was expected to continue its growth of 7% to 8% per year and to comprise 30% of the fluorocarbon market, up from the former 28%.[4]

E. I. du Pont reportedly plans to build the world's largest fluorocarbon facility at Corpus Christi, Tex., with an initial annual capacity of 250,000 tons of fluorine chemical intermediates,[5] such as Freon and other fluorocarbons used for refrigeration, air conditioning, aerosol propellants, solvents, dry cleaning, fire extinguishers, and food processing. No estimate was given as to the tonnage of acid-spar or HF that would be required to make the 250,000 tons of fluorocarbons. The construction of this plant and the expansion of others verify the accelerated growth in fluorspar consumption as predicted by Noble and Jones.[6]

Consumption of acid-spar by the aluminum industry can no longer be directly related to growth in the industry because of many recent operating changes. U.S. aluminum ingot production for 1972 increased 5% over the 1971 production, whereas world output gained only 4%.[7] Acid-spar consumption in electrolytic potlines did not match this growth rate in 1972, nor is it expected to for 1973. With the advent of emission controls by Federal and State environmental protection agencies, and the high 1972 prices for acid-spar, aluminum companies successfully started salvaging emitted fluorine-bearing particulates and gasses. The emission control efficiency ranged from zero at plants without controls to about 94% at plants with control systems. The average was about 73%. About half (46%) of the fluorine emitted was in the gaseous state, and the remainder in the solid state. In those plants having efficient emission control, the companies salvaged and recycled the fluorine-bearing particulates by feeding them directly into the reduction cell. By 1972, the recycled, salvaged fluoride compounds from the potlinings and from the emitted particulates were estimated to have reduced by about 11% the consumption of primary fluorine from 140 pounds of CaF_2 to 125 pounds.

[7] American Metal Market. Primary Aluminum Demand Rising: Irving Lipkowitz of Reynolds Metals Co., Dec. 15, 1972, p. 17.

In the absence of any fixed consumption rate, it was estimated that 125 pounds of acid-spar was required per ton of aluminum produced. Except for a small percentage of acid-spar that is added to the electrolytic potline as a flux, the major tonnage of fluorine salt fluxes, Na_3AlF_6 and AlF_3, were made from HF. In 1972, 4,112,000 tons of aluminum were produced in the United States; and theoretically, about 257,000 tons of acid-spar were used. However, in 1972 about 39,000 tons of H_2SiF_6, a byproduct of the phosphate fertilizer industry, was used to make Na_3AlF_6 and AlF_3. This new substitute source thus reduced by 55,000 tons the primary demand of acid-spar from 257,000 tons to about 202,000 tons or 15% of U.S. consumption.

Fluorine as HF is used in the nuclear reactor industry to produce stable uranium tetrafluoride (UF_4) by reacting UO_2 with anhydrous HF. Subsequently, when needed, fluorine gas is added to the UF_4 to make unstable uranium hexafluoride (UF_6) before feeding into the diffusion plant for separation of U-235 and U-238. The spent UF_6 (minus U-235) is stored in pressurized metal tanks.

Theoretically, there is almost an equal amount of fluorine in 1 ton of 97% CaF_2 as there is in 1 ton of UF_6, but in processing through the stages from CaF_2 to HF and to UF_4 or UF_6 some fluorine is lost. It is reported that about 1.5 to 1.66 tons of acid-spar were required to produce 1.0 ton of UF_6. The 1972 fluorine requirement for domestic nuclear power reactors, as reported by the U.S. Atomic Energy Commission (AEC) was estimated at 3,000 tons of fluorine, which is equivalent to at least 6,000 tons of acid-spar. The demand is conservatively anticipated to increase 2 times in the next 5 years and accelerate thereafter. Of the UF_6 fed to the gaseous diffusion plant about 15% was withdrawn in the enriched uranium product. The remainder was left in the waste stream and probably stored as UF_6. There is no known commercial recovery of fluorine from UF_6, but the AEC has recovered some for its own use.

If all the UF_6 in the waste stream could be converted to UF_4 and then salvaged as anhydrous HF for reuse, about 20% to 25% less primary fluorine would be required. No information was available on the amount of UF_6 being produced at two known commercial plants or that is in stocks of fluorine products held by these companies. No information is available on the UF_4 or UF_6 stocks held by the AEC. The estimated amount of CaF_2 used to make HF and then distributed to making UF_6 and UF_4 ranges from 2% to 4% of the total CaF_2 used to make HF.

The consumption of fluorine as a liquid fuel in the space program has been mentioned in the literature. In 1971 and 1972 all testing for use of fluorine in rockets was performed in a closed circuit permitting reuse of the fluorine. The use of fluorine in space booster rockets or burns for handling the shuttle platform is being considered, but if it is used, the consumption would be minor.

STOCKS

Producers stocks of finished fluorspar were reduced 46% and consumers stocks were reduced 13%, which is another indication that neither the producers nor consumers were worried about inadequate supplies. More than necessary stockpiles of fluorspar were reported to exist in Mexico, Thailand, Spain, and the Republic of South Africa.

PRICES

Prices of standard finished fluorspar material did not increase significantly from 1971 to 1972. According to the U.S. Bureau of Mines canvass and to verbal information, the spread between the quoted low and high prices was greater in 1972, ranging from \$55 to \$87.50 per ton for acid-spar, from \$42 to \$57 for gravel spar, and from \$65 to \$95 for fluorspar pellets of variable CaF_2 content. Some spot purchases for quality acid-spar were about \$66.50 per ton delivered to the consumer.

Fluorspar prices in foreign countries varied greatly. In Europe they were generally higher, 18% to 34%, due primarily to the decrease in value of the U.S. dollar on the European exchange market. As shown in table 9 the value of acid-grade fluorspar f.o.b. foreign port ranged from \$55 to \$87 per ton in Italy, and from \$62 to \$69 in Spain. In Mexico, where U.S. prices are established, acid-spar values increased 22% and averaged about $42 per ton f.o.b. foreign port, and met-spar values increased about 35% and averaged about $28 per ton.

Met-spar prices in Thailand, the second largest producer in the world, dropped in the last quarter of 1972 and were quoted at yearend at $35 to +$38 per ton f.o.b. Bangkok.

Because over 53% (table 5) of U.S. consumption of fluorspar is used to make HF, the trend of the HF market is important. In 1972 the price of 70% aqueous HF ranged from $400 to $560 per ton.

[1] Prices reported in the Engineering and Mining Journal do not reflect the soft market for flourspar that developed during the last quarter of 1972.

Source: December issues of Engineering and Mining Journal, 1971 and 1972.

FOREIGN TRADE

Exports continued to be of minor importance in 1972; about 2,300 tons out of a total of 2,700 tons were shipped to Canada. On the other hand, imports of fluorspar were nearly 711,000 tons, an increase of 23% over the 1971 level. As in 1971, two-thirds of the fluorspar imports came from Mexico and the rest mainly from Spain and Italy.

WORLD REVIEW

Australia.—Production of fluorspar in 1972 was limited to byproduct extraction and some test shipments. Many fluorspar deposits have been discovered, mostly in southern Australia. Some of those delineated by drilling were reported to be of the million-ton size, but either the reports were false or the development work required has prevented these discoveries from getting into production. Rising domestic demand for both met-spar and acid-spar is expected to stimulate Australian production in the near future.

Fluorspar consumption by the Australian steel and aluminum industries totaled about 37,000 tons in 1970, 40,000 tons in 1971, and possibly 40,000 tons in 1972. Consumption is expected to more than double in the next 5 years as new steel plants and HF plants are built. New HF plants were announced by Australian Fluorine Chemical Co. Ltd. to be built at Kooragang Island, New South Wales, and by Australia Fluorine Chemicals Pty. Ltd. at Newcastle, New South Wales.

[e] Estimate. [p] Preliminary. [r] Revised.

[1] In addition to the countries listed, Bulgaria and Morocco also produce fluorspar, but information is inadequate to make reliable estimate of output levels.

[2] Includes materials recovered from lead-zinc mine dumps.

[3] Data are for year ending June 30, of that stated.

Canada.—Production resumed at better than normal rate in 1972 after the drastic dropoff in 1971 due to labor strikes. The 180,000 tons produced in 1972 was mostly acid-spar, predominantly produced by New Foundland Fluorspar Ltd., a subsidiary of Aluminum Company of Canada (Alcan). The bulk of Canada's production continues to come from the Burin Peninsula, near the village of St. Lawrence, Newfoundland. In May 1972 Alcan announced the development of a new fluorspar mine at St. Lawrence, Newfoundland, to replace the decreasing production from some of the older mines. The new mine is scheduled for production in 1976 and initially will produce 500 tons per day.[8] Nearly all of Alcan's acid-spar production was used in the firm's aluminum smelting facilities at Arvida, Quebec, where it is first processed into synthetic cryolite.

A recent announcement by International Mogul Mines Ltd. indicates that a large barite-fluorspar deposit has been developed on the east side of Lake Ainslie in Inverness County, Cape Breton Island, Nova Scotia. The barite-fluorspar veins occur in welded rhyolite tuffs, and are localized at or near the fault contact with a siltstone-shale formation. The inferred reserves total about 4 million tons containing ore assaying 28% to 50% barite and 17% to 19% fluorite. Exploitation of these deposits is not considered economically feasible at this time owing to high mining and milling costs, but production from this paramarginal deposit could become a reality if some of the metallurgy could be solved, or if the price of acid-spar increased slightly.

No production was reported from Consolidated Rexspar Minerals & Chemical's uranium-fluorspar prospect in the Birch Island area, British Columbia, or from the Conwest Exploration-Jorex partnership in the Fort Nelson (Laird River) area of northern British Columbia. Many other international companies were actively exploring in Newfoundland and British Columbia during the year.

Canadian imports of fluorspar decreased in 1972, to 72,000 tons. The 225,000 tons total imported in 1971 was unusually high because of the shutdown of Canadian mines for about 5 months.

France.—Production from France re-

[1] Details on origin, unless otherwise specified, are from import data of countries listed as destinations, and figures in the total receipts column for each listed destination, are summations of reported imports of the listed destinations. Figures in the column headed total recorded exports are from the export statistics of the listed source countries. Differences between total receipts and total recorded exports are attributed chiefly to the time lag between date of shipment and the date of receipt, but some differences may result from either: 1) concealment policies of some countries, and/or 2) reshipment of material by intermediate countries which may be credited as the origin in the trade returns of final recipient countries.

[2] Data are for year beginning July 1, 1971.

[3] Data are for 11 months only; January, February, and April through December.

[4] Countries included and total imports by each in short tons are: Denmark—2,741; Finland—6,635; France—6,162; and Yugoslavia—5,409.

[5] The Netherlands recorded 19,195 tons total imports from undisclosed origins; Argentina recorded the export of 30,595 tons to the Netherlands in 1971. Presumably, the bulk, if not all, of the material of undisclosed origin was from Argentina and on this assumption it has been so credited.

[6] West Germany records 152,877 tons total imports from undisclosed origins (plus 213 short tons from countries specifially identified but not listed separately as origins in this table). France records the export of 69,070 tons to West Germany in 1971. On the basis of this export report, 69,070 tons has been credited to France and the other and/or undisclosed total has been reduced by a like amount.

[7] Mozambique reports no production or exports of fluorspar; apparently the imports recorded by four nations from Mozambique were shipped from other countries by way of Mozambique.

[8] Less than ½ unit.

[9] Includes 35,704 tons credited to Algeria and 8,901 tons credited to Greece, neither of which are known to be a fluorspar producer.

[10] Recorded receipts by the U.S.S.R. from Japan exceed both recorded Japanese production and exports. Japan reported the export of 6,835 tons to the U.S.S.R. in 1971; presumably the balance of the Soviet import credited to Japan was material shipped to the U.S.S.R. by way of Japan.

[11] Official estimate by The Government of the United Kingdom.

[12] The United States records 12,367 tons total imports from Switzerland, but there is no known production from that country.

mained the same at about 410,000 tons. France is self-sufficient in fluorspar, supplying all of its internal demands, and also exporting some to Austria, Belgium, Italy, West Germany, and Japan. The industry is dominated by the Péchiney-Ugine-Kuhlmann combine and Société Denain-Anzin, which consume most of their acid-spar production. Output of about 10 other smaller met-spar producers goes mostly to supply local demands.

Italy.—Italian mines produced about 306,000 tons in 1972, a small reduction from the 318,000 tons produced in 1971. However, Italy maintained its position as sixth largest producer in the world. Production is still dominated by two companies, Mineraria Silius S.p.A. of the C.E. Giulini group and the Montedison Mines Division of Montecatini-Edison S.p.A. Mineraria Silius is the world's largest individual producer of acid-spar, with a reported capacity of 250,000 tons annually. The operating companies continued to increase their identifiable reserves, which are reported to be over 14 million tons of ore averaging about 50% CaF_2.

Although Italy is a large exporter of acid-spar, it imports met-spar from France, Mexico, and the Republic of South Africa. Feasibility studies are still continuing on plans to pelletize the pyroclastic tuff and carbonatite deposits in the Castel Giuliano district, located north of Rome, to produce a 70% CaF_2 met-spar.

Japan.—Japan is the second largest consumer of fluorspar in the free world. Preliminary estimates indicate that the Japanese imported 414,600 tons of met-spar in 1972, and about 125,700 tons of acid-spar. The consumption ratio of met-spar to acid-spar was about 3⅓:1. The Japanese steel industry consumed most of the met-spar, but the Japanese chemical industry also upgraded considerable met-spar to make acid-spar and then HF. Japanese mines produce small tonnages of met-spar, usually equivalent to only a few percent of the imports.

In 1971 Japan imported 747,000 tons of fluorspar, much more than its requirements. During 1972, total imports were cut nearly 206,000 tons and the steel and aluminum industries drew heavily on stockpiled supplies. Imports from Thailand decreased from about 321,000 tons in 1971 to 252,000 tons in 1972, and imports from the Republic of South Africa were reduced from 149,000 tons to 115,000 tons. However, imports from the People's Republic of China, the third major supplier, went up slightly from 107,000 tons in 1971 to 118,000 tons in 1972. Japanese fluorspar-consuming industries like those in United States intensified their research to reduce the amount of fluorspar consumed per unit made. A mild recession in the steel and aluminum industries, also reduced the total Japanese consumption.

Nikkei Sangyo, a subsidiary of Nippon Light Metal Co. Ltd. announced the construction of the world's first commercial plant for the production of what is claimed to be a fluorspar substitute based on "red mud." The Nikkei Sangyo process blends red mud with other alumina-containing material before moulding and drying. The product known as "Alblack" contains 40% to 45% alumina, 20% to 25% iron oxide, and 8% to 10% silica, and is available as granules or as briquets. Commercial production was scheduled to start in September 1972; but, as yet, no actual figures on its effectiveness and on the quantity required per ton of steel have been released.[9]

Mexico.—Mexico maintained its position as the leading producer of fluorspar in the world, and continued to be the largest exporter to the United States, providing 78% of U.S. imports. Mexican exports to the United States averaged about half acid-spar and half met-spar, with total exports to the United States increasing about 9% in 1972. However, Mexico's world exports did not increase, and a few Mexican producers had trouble selling their ore. Some small fluorspar mines closed down, but the major producers continued at normal production rates. Table 11 indicates that Mexico's production dropped from 1,302,000 tons in 1971 to 1,149,000 tons in 1972.

Mexico's consumption of met-spar decreased in 1970–71 because the local steel industry had difficulties. In 1972, however, most of the steel plants resumed production, and programs to enlarge old plants and construct new BOF plants were announed.[10] The proposed new BOF steel plants, if constructed, will approximately double Mexico's consumption of met-spar.

Although the industrial recession of 1971 retarded investments in Mexico's chemical industry, expansion plans announced by yearend 1971 and early 1972 indicated a dramatic growth for the future, including expansion plans for new HF plants.

Two small HF plants continued to consume a little acid-spar. Most of the HF is used in the chemical industry, and a little is exported to the United States.

Progress was made on the HF plant being built west of Matamoros by Química Fluor, S.A. de C.V., which is jointly owned by the Mexican Government (Comisíon de Fomento Minero), E. I. du Pont de Nemours, Minero Frisco S.A., and Banco de Comercio. Du Pont is building the plant and will operate it for Química Fluor.

[9] Industrial Minerals. Interest Grows in "Red Mud" Substitute for Fluorspar. V. 60, September 1972, pp. 34, 35.

[10] U.S. Consulate General, Monterrey, Mexico. Iron and Steel: Fundidora Expansion Plans. State Department Airgram A–70, Dec. 19, 1972, p. 2.

This 70,000-ton-per-year plant is expected to go on-stream in 1975.

Metalúrgica Mexicana Peñoles S.A., Fluorita de Rio Verde S.A., and Continental Ore Corp. jointly announced the construction of a fluorspar flotation plant of 3,600-ton annual capacity. This plant was being built near the mines in the Alamos de Martinez district in Guanajuato, about 45 miles south of the Rio Verde district in San Luis Potosi, to utilize the waste piles.[11]

The Las Cuevas mine, which is owned by Sierra Minera Las Cuevas, a Noranda Mines Ltd. associate, is the largest fluorspar mine in the world. In 1972, a new flotation plant completed its first full year of operation. All told, the Las Cuevas mine produced 30,000 tons of acid-grade and ceramic-grade concentrates plus about 249,000 tons of gravel met-spar. This compares with the 356,000 tons total produced in 1971. Large stockpiles of fluorspar fines are available at this mine located in San Luis Potosi; these constitute the waste material derived from the met-spar washing and jigging plant.[12]

South Africa, Republic of.—Fluorspar production decreased 12% to 232,000 tons. Exports to the United States increased 135%, and most of the increase was in met-spar. There are five known fluorspar mines with concentrating plants plus five other mines producing small tonnages of met-spar.

Recent ore discoveries resulted in the opening of new mines and in a sharp increase of total economically minable reserves to over 50 million tons of 35% CaF_2 equivalent.[13]

A characteristic of the larger open pit mines in the Republic of South Africa is that ore grade runs only 15% to 20% CaF_2, with some as low as 10% CaF_2. However, one large operator is known to maintain a mill feed of 35% CaF_2.

In the Transvaal district, General Mining and Finance Corp. operates the Buffalo open pit mine and produced both acid-spar and met-spar. Mill feed ranged from 13% to 25% CaF_2, and mill capacity was reported at 150,000 tons annually. Some small mines in the district produced met-spar.

In the nearby Warmbath area, Montrose Exploration owned by Gold Fields of South Africa Ltd. and Allied Chemical Co. operated the Zwartkloof open pit fluorspar mine. A large reserve of 25% CaF_2 ore has been delineated. A flotation mill of 1,500-ton-per-day capacity reportedly produced a concentrate ranging from 91% to 97% CaF_2. In the Marburg district, a 45% CaF_2 ore is mined by small operators and upgraded by hand sorting and some mechanical jigging to produce met-spar.

Other companies active in fluorspar exploration and mining in the Republic of South Africa included the Vergenoeg Mining Co., the Ottoshoop Holdings, the Phelps Dodge-Minerva joint venture, U.S. Steel Co. (through the subsidiary Monico Fluorspar Co.), and the Transvaal Consolidated Land Co.

Spain.—Although production from Spain showed a dramatic increase of 23%, from approximately 437,000 tons in 1971 to 537,000 tons in 1972, the figures are questionable. Some of the production appears to be crude ore rather than finished product. Nonetheless, the country ranked somewhere between second and fourth in the world as a fluorspar producer. Spain consumes little of its production, and exports most of it to the United States, Belgium, and West Germany. Capacity is currently in excess of output, and development activities by the two main producers and others should lead to additional production in the future. Spain's fluorspar reserves are sufficient to justify expansion.

Thailand.—Thailand struggled through 1972 to maintain its position as one of the largest fluorspar producers in the world. The slump in world demand adversely affected Thailand's output, with a resultant production drop of 7.5%, from 471,000 in 1971 to 435,000 tons (70% CaF_2) in 1972 and a value decline from $42.83 per ton in 1971 to $38.09 per ton in 1972, f.o.b. Bangkok. The reported fluorspar price at the mine (loaded on truck or railroad car) averaged $35.70 per ton. Exported tonnage decreased 23% from 370,000 in 1971 to 258,000 tons in 1972. Fluorspar was Thailand's fourth largest mineral export commodity in 1972, but the total export value decreased to $10.2 million in 1972, f.o.b. Bangkok. Japan continued to be the largest buyer, receiving 229,014 tons at an average cost of $41.51 per ton c.i.f. Japanese port. The number of operating fluorspar mines in Thailand ranged from 50 to 81, but on the average there were 69 mines employing about 7,000 men.

---

[11] Industrial Minerals. Metalurgica Mexicana Penoles S.A. No. 57, June 1972, p. 53.

[12] Noranda Mines Ltd. 1972 Annual Report. Toronto, Canada, April 1973, 15 pp.

[13] Hodge, B. L. World Fluorspar Developments 2. Ind. Miner., June 1973, pp. 9, 10.

Consumption of met-spar by the small Thai steel industry was not reported for 1971 or 1972. Total domestic consumption of fluorspar probably has been less than 10,000 tons per year. Thailand's stocks of fluorspar at yearend 1972 were probably close to 100,000 tons.

The Thai Fluorite Processing Co. Ltd.'s concentrating plant located in Petchaburi Province went on-stream in July 1972, and was officially dedicated in September 1972. This company produced about 11,000 tons of 98% CaF_2 fluorspar concentrate during 1972. Actually, Thai Fluorite's annual rated capacity is 55,000 tons of concentrate containing more than 97% CaF_2. Reportedly, Thai Fluorite has a contract with Ataka Trading Co. of Japan to deliver up to 33,000 tons of acid-spar before March 31, 1973, and an additional 33,000 tons before March 31, 1974.[14]

In March 1972, Universal Mining Co. Ltd. completed a heavy-media separating plant in the Ban Hong district near Chiengmai, Lamphun Province, about 330 miles north of Bangkok. The plant was designed and built by Head Wrightson Process Engineering Ltd. of the United Kingdom. Full production was not achieved until December. The feed is reported to come from piles of waste material accumulated in the area during the past 10 years. Reportedly the plant is expected to produce 60,000 tons of about 80%-grade fluorspar annually.[15] Crude ore from nearby mines will also be available for processing.

Leighton Mining N.L. of Australia obtained a 49% interest in Petchaburi Mining and Processing Ltd., which has been operating fluorspar mines in south-central Thailand. Historically, Petchaburi Mining has produced 30,000 tons of handsorted met-spar annually.[16] This acquisition is an indication that Australian companies are interested in obtaining a source of fluorspar for the growing steel industry in Australia.

Toyoda Tsusho Co. of Nagoya, Japan has obtained an interest in some fluorspar mines in Lamphun Province. The reserves are reported to be 150,000 tons, which may be mined by crude hand methods to produce met-spar at the rate of 3,000 tons per month.[17]

Thai fluorspar producers are aware that the People's Republic of China has made trade agreements to ship an additional 50,000 tons of met-spar annually to Japan. Thai producers hope to make up this market loss by selling at least twice that amount to the Soviet Union. Soviet trade may present transportation problems owing to a dearth of Soviet ships stopping at Bangkok.

Large-scale systematic exploration and mining are not common in Thailand. Apparently, only the most visible and accessible deposits have been mined thus far. No fluorspar reserve figures are known to have been published, but overall resources are substantial, probably exceeding 8 million tons of 50% CaF_2.

United Kingdom.—Fluorspar production in the United Kingdom decreased about 10% to 243,000 tons in 1972. Approximately four major companies and nine minor companies apparently were in operation during the year. In addition, there were eight other companies actively exploring for fluorspar. The United Kingdom continued to be self-sufficient with respect to fluorspar requirements, and there were substantial exports to several countries. United Kingdom exports were estimated to be over 40,000 tons, mostly acid-spar, in 1972. Exports may decrease, however, as demand for fluorspar by the three new domestic aluminum producers increases.[18]

TECHNOLOGY

A continuous process for the production of aluminum fluoride (AlF_3) from fluosilicic acid (H_2SiF_6) has been proposed by P. M. R. Versteegh and Thomas J. Thoonen of Unie van Kunstmestfabrieken in a paper given before the Fertilizer Society of London. The H_2SiF_6 is recovered by standard scrubbing processes in a phosphoric acid plant; then ammonia is reacted with the H_2SiF_6 to produce ammonium fluoride and to precipitate the silica and hydrated triammonium phosphate; then the ammonium fluoride is reacted with gibbsite, the source of aluminum, and after drying and calcining, AlF_3 is produced. This product with cryolite is essential as a flux in the electrolytic potlines to produce aluminum.[19]

[15] Industrial Minerals. Progress in Modernising Thailand's Fluorspar Industry. No. 56, May 1972, pp. 31-33.

[16] Industrial Minerals. No. 58, July 1972, p. 37.

[17] Industrial Minerals. New Fluorspar Mine in North. No. 60, September 1972, p. 37.

[18] Hodge, B. L. World Fluorspar Developments. Ind. Miner., No. 69, June 1973, pp. 5-31.
Guccione, E. What's Going On in the Fluorspar Industry. Eng. and Min. J., v. 173, No. 12, pp. 64-75.

Aluminum Co. of America at Ft. Meade, Fla., has been manufacturing AlF_3 probably by a similar process since 1971. This source of fluorine may become more common as more phosphoric acid plants are forced, due to economic or environmental reasons, to recover H_2SiF_6. More than 20 plants throughout the world are reported to be recovering H_2SiF_6.

In the United States the seven phosphoric acid plants known to be recovering H_2SiF_6 in 1972 recovered 65,100 tons of 100% H_2SiF_6. This was about 30% of the maximum total of 213,000 tons that could be recovered if all the phosphoric acid plants recovered H_2SiF_6. Approximately 40% of the H_2SiF_6 was sold for public water fluoridation, and 60% was sold to make inorganic salts for the aluminum industry. Therefore, about 39,000 tons was used by the aluminum industry, and by assuming a replacement ratio of about 1.4 tons of CaF_2 per ton of H_2SiF_6, the equivalent of 55,000 tons of CaF_2 was substituted by H_2SiF_6.

In December 1972 Reynolds Metals Co. announced that it would spend almost $6 million during 1973 on antipollution equipment at its Corpus Christi, Tex., aluminum complex. Most of the money will be spent to install electrostatic precipitators, covered conveyor systems, hoods and domes, and a tri-gas fluxing system primarily to reduce particulate and gas emissions at the electrolytic aluminum potlines. This action will undoubtedly increase recovery of fluoride compounds as particulates and fluorine gases, which may be recycled, and reduce the primary demand for Na_3AlF_6 and AlF_3.[20]

New uses for CaF_2 slags with a variable percent of AlF_3, LaF_3, and YF_3 at 1,500° to 1,600° C for electrical conductivity of metal liquids have been determined.[21]

Aluminum fluoride probably has found a new, but limited, use in the froth flotation of quartz, feldspar, and corundum by absorption or by reaction in an HF solution. The best separation of quartz took place in the acid solutions (accompanied by some formation of SiF_6). This research work has also progressed into the use of H_2SiF_6 and sodium fluosilicate (Na_2SiF_6) as activators.[22]

The American Medical Association (AMA), after the death of dogs that had breathed high concentrations of fluoroalkane gases in laboratory tests, warned the public to be careful when using aerosol sprays. The AMA also recommended against humans sniffing these gases. Laboratory tests have not been conclusive as to whether the deaths were due to a lack of oxygen or to the gases that may cause lung lesions.[23]

The Federal Bureau of Mines research centers are conducting research programs to offset the U.S. deficiency of fluorspar. Studies are continuing on the economic availability of fluorine recovered from the byproduct fluosilicic acid, and on methods to increase fluorspar or fluorine recovery from subgrade fluorspar ores, mill tailings, and industrial wastes.

CRYOLITE

Officially reported U.S. imports of cryolite (natural and synthetic) increased 11% to 26,000 tons in 1972. The bulk of the imports was synthetic cryolite. The largest supplier was said to be Japan, which supposedly furnished more than 10 times the tonnage exported in 1971. Japanese export figures do not confirm this, and it is suspected that transshipments from elsewhere might be included. Almost all of the Japanese shipments were synthetic cryolite. U.S. import values have not been presented in table 13 this year because of the uncertainty of reported values.

As in past years, Greenland was the only world produces of natural cryolite. During 1972 Greenland produced 65,000 tons of cryolite ore, probably from the tailings piles or dumps at the Ivigtut mine, and the ore probably assayed 50% to 60% cryolite.[24] The destination of this ore was not reported, but it was probably shipped to the Kryolitselskabet Oresund plant at Copenhagen, Denmark, where for many years the Greenland ore has been crushed, upgraded, and processed. The prime product is cryolite, but the byproducts like fluorspar, siderite, and sulfides are also produced. The Kryolitselskabet Oresund plant has a flotation section with a concentrate output capacity of about 30,000 tons annually. In 1972 Denmark exported 989 tons to the United States of what was probably natural cryolite.

For many years the Pennsylvania Salt Manufacturing Co. at Natrona, Pa., also refined cryolite ore shipped from Greenland. This company had the exclusive North American rights for processing and distribution, but in 1972 no U.S. cryolite imports from Greenland were reported.[25]

Table 13.—U.S. imports for consumption of cryolite

Year and country	Quantity (short tons)
1969	20,406
1970	21,399
1971:	
Belgium-Luxembourg	(1)
Canada	4,584

Gallium

By E. Chin [1]

Domestic production of gallium in 1972 increased sharply over production in the previous year. Most of the gallium consumption was for the production of gallium intermetallic compounds used in light-emitting diodes for electronic visual display panels. Sales of gallium-arsenide-phosphide for optoelectronic devices were estimated at $14.5 million in 1972, up from $4 million in 1971.

DOMESTIC PRODUCTION

Production of gallium metal in 1972 by two companies was more than double that in 1971. The sharp rise in production was attributed to increased demand for gallium by the electronics industry.

Gallium metal was produced as a byproduct of alumina production by the Aluminum Company of America (Alcoa) at its Bauxite, Ark., plant. Gallium metal, oxide, and trichloride were produced by Eagle-Picher Industries, Inc., at its Quapaw, Okla., plant. Production data are company confidential. In addition, gallium metal and compounds produced primarily from imported material were supplied by Alusuisse Metals, Inc., Atomergic Chemetals Co., Cominco American, Inc., European Electronics, Inc., B. Freudenberg, Inc., Indium Corporation of America, Kawecki Berylco Industries, Inc., and Ventron Corp.

Alcoa announced a breakthrough in production technology which reportedly will enable the company to triple its gallium production capacity at the Bauxite, Ark., plant. Additional gallium production may be possible at Alcoa's refineries at Mobile, Ala., and Point Comfort, Tex.

Canyon Land 21st Century Corp. (Canyon Land), Blanding, Utah, is expected to begin production of gallium in late 1973. Canyon Land will use as its raw material source, gallium contained in phosphate residues, which will be provided by the Monsanto Company.

CONSUMPTION

The largest use of gallium was in electronic applications, principally in the form of gallium arsenide and gallium phosphide, which are used in solid state lamps (light-emitting diodes, LEDS). Due to the pronounced trend of the electronics industry towards microminiaturization, LEDS were increasingly used in visual display systems in calculators, digital clocks, medical instrumentation, multiple warning lights, and instrumentation for aircraft and automotive dash panels. A novel use for LEDS was in the production of electronic watches in which the time display system is based on a gallium lamp matrix. The manganese-doped magnesium-gallium spinel ($MgGa_2O_4$:Mn) is a green phosphor used in ultraviolet excitation and is used in fluorescent lamps in Xerox copying machines. Gallium compounds were also used in semiconductor applications for microswitching devices and in microwave and laser applications. The intermetallic compound vanadium-gallium, V_3Ga, is a superconductor with a high transition temperature and a high critical field.

In research and development there was growing interest in the gadolinium-gallium garnet, $Gd_3Ga_5O_{12}$, as a substrate material for magnetic bubble domain devices. Gallium trichloride was investigated as a Friedel Crafts reagent in organic synthesis.

Total	2,288,882	5,076,205

p Preliminary.

[1] Dental, brazing, and specialty alloys.

[2] Primarily for light-emitting diodes; includes semiconductors and color television phosphors.

Approximately 98% of the gallium consumed in 1972 was for electronic applications. Major consuming firms included Bell and Howell Co., Bell Telephone Laboratories, Inc., Fairchild Research and Development Laboratories, Hewlett-Packard Laboratories, Laser/Diode Laboratories, Inc., Litronix Inc., Monsanto Company, Motorola, Inc., Opcoa, Inc., RCA Corp., Texas Instruments, Inc., Texas Materials Laboratories, Inc., and Western Electric Co.

Strata Physics, Inc. (Strata), a user of gallium compounds for the production of optoelectronic materials, doubled the size of its plant at Santa Clara, Calif. Orders for Strata's optoelectronic materials in 1972 were reportedly over $2.4 million.

STOCKS

Consumer stocks of gallium metal, low- and high-purity grades, totaled 1,175,899 grams as of December 31, 1972. Stocks a year earlier were 187,678 grams. Shipments of gallium metal as reported by producers, dealers, and traders in 1971 and 1972 were, respectively, 853,069 grams and 3,157,634 grams. Gallium metal stocks, in grams, as held by producers and suppliers were as follows:

Year	January 1	December 31
1971	211,362	402,875
1972	402,875	1,005,945

PRICES

The average price per gram of gallium metal as quoted by domestic producers in 1972 were as follows:

Quantity	Purity designation		
	99.99%	99.999%	99.9999% 99.99999%
50 to 999 grams	$0.90	$1.05	$1.20
1,000 to 4,999 grams	.60	.65	.80
5,000 to 24,999 grams	.55	.60	.75

For orders over 500 kilograms of gallium between 6–9's and 7–9's purity, the selling price of metal was reportedly between $0.60 and $0.65 per gram. The price of a single LED unit as quoted by Monsanto Company was as follows:

Color	Composition	Quantity			
		1–9	10–99	100–999	Over 1,000
Amber	Gallium-arsenide-phosphide	$1.50	$1.50	$1.15	$0.99

FOREIGN TRADE

Exports of gallium are not reported separately and are included in base metals and alloys, not elsewhere classified, wrought or unwrought, waste and scrap.

Total U.S. imports of gallium in 1972 were 13,372 pounds valued at $2,715,179, compared with 5,889 pounds valued at $1,182,118 in 1971. The unit value of gallium imports ranged from $290 per kilogram for material from Italy to $530 per kilogram for gallium from the United Kingdom. The average unit value of all gallium imports in 1972 was $415 per kilogram.

Table 3.—U.S. imports for consumption of gallium (unwrought, waste and scrap), by country

Country	1971		1972	
	Pounds	Value	Pounds	Value
Canada	587	$129,844	3,077	$696,186
Germany, West	403	70,712	274	45,479
Hong Kong	--	--	9	1,426
Hungary	--	--	4	680
Italy	--	--	344	45,369
Japan	1	364	34	5,985
Netherlands	133	32,698	322	74,015
Switzerland	4,319	854,662	9,099	1,795,792
United Kingdom	[1] 446	[1] 93,843	209	50,247
Total	[1] 5,889	[1] 1,182,118	13,372	2,715,179

[1] Adjusted by the Bureau of Mines.

WORLD REVIEW

Canada.—Chemalloy Minerals Limited (Chemalloy) of Toronto agreed to ship samples of the tailings containing gallium from its tantalum mining operation at Bernic Lake, Manitoba, to Cominco Ltd., Kawecki Berylco Industries, Inc., and Eagle-Picher Industries, Inc. to investigate gallium extraction from the tailings. The mine at Bernic Lake, about 100 miles north of Winnipeg, is operated through Chemalloy's wholly owned subsidiary, Tantalum Mining Corp. of Canada Limited (Tanco). In addition to tantalum ore, Tanco mines pollucite, a cesium raw material source.

Tanco obtained research assistance from the University of Manitoba and financial aid from the Manitoba Research Council to investigate gallium recovery from the Bernic Lake operation. The study includes the determination of the point of maximum concentration of gallium in the process of recovering tantalum and the development of a gallium extraction process.

Cominco Ltd. recovered gallium as a byproduct from its zinc plant at Trail, British Columbia.

Japan.—Gallium production in Japan for 1968–72, estimated by the Japan Society of Newer Metals, was as follows:

Year	Kilograms
1968	100
1969	150
1970	175
1971	210
1972	500

Gallium production in 1972 was by the Dowa Mining Co., Ltd. and Nippon Light Metal Co., Ltd. Gallium intermetallic compounds were manufactured by Mitsubishi Metal Corp., Nippon Light Metal Co., Ltd., Sumitomo Electric Co., Ltd., and Sumitomo Metal Mining Co., Ltd.

Sumika Alusuisse Gallium Ltd. (Sumika), a joint venture between Swiss Aluminium Ltd. (Alusuisse) and Sumitomo Chemical Co., was formed in Japan to produce gallium metal as a byproduct of alumina production. Sumika was to establish a $2.5 million plant at Nijhama with a gallium production capacity of 2,000 kilograms per year; initial startup was scheduled for late 1973. Alusuisse was to provide the technical know-how for the installation and operation of the plant.

Dowa Mining Co., Ltd. (Dowa) increased its gallium production capacity from 5 kilograms per month to 100 kilograms per month at its Kosaka (Akita Prefecture) plant. The gallium raw material source for the Kosaka plant was from residues from the Iijima zinc smelter which is operated by Dowa's subsidiary, Akita Zinc Co. (Akita Zinc). Akita Zinc reportedly produced sufficient residue to allow recovery of 200 kilograms of gallium a month.

Netherlands.—N. V. Billiton Maatschappij (Billiton), in partnership with Kawecki Berylco Industries, Inc. (KBI), formed N. V. Kawecki-Billiton Metaalindustrie (Kawecki-Billiton), which replaced the Special Metals Division of Billiton. KBI became the exclusive sales agent in the United States and Canada for Kawecki-Billiton's ultra-high-purity metals which, in addition to gallium, include antimony, arsenic, bismuth, cadmium, copper, gold, indium, lead, tellurium, and tin.

World producers of gallium by company, location, and raw materials source are as follows:

Country	Company	Location	Source
Canada	Cominco Ltd	Trail, British Columbia	Zinc ore.
China, People's Republic of	NA	NA	NA.
Czechoslovakia	NA	NA	NA.
France	Alusuisse France S.A	Marseilles	Bauxite.
Germany, West	Martinswerk G.m.b.H. fur Chemische und Metallurgische Produktion.	Bergheim/ Erft.	Do.
Hungary	NA	NA	NA.
Italy	Società Alluminio Veneta Azioni	Porto Marghera	Bauxite.
Japan	Dowa Mining Co., Ltd	Kosaka	Zinc ore.
	Nippon Light Metal Co., Ltd	Shimizu	Bauxite.
	Sumika Alusuisse Gallium Ltd	Nijhama	Do.
	Toho Zinc Company	Fujioka	Zinc ore.
Norway	Vigeland Metal Refinery A/S	Vigeland	High-purity aluminum.
Switzerland	Alusuisse Research Laboratories	Neuhausen am Rheinfall.	Crude gallium metal.
U.S.S.R	NA	NA	NA.
United States	Aluminum Company of America	Bauxite, Ark	Bauxite.
	Eagle-Picher Industries, Inc	Quapaw, Okla	Zinc ore.

NA Not available.

TECHNOLOGY

International Business Machines Corp. announced the development of a new type of solar cell that is more efficient than existing cells in converting sunlight to electricity.[2] The new solar cell was capable of converting 18% or more of the energy of the sunlight into electricity, older cells were typically 11% to 13% efficient. The cell is composed of a gallium arsenide layer and a layer of gallium-aluminum-arsenide doped with zinc atoms. The new cell reportedly could operate at higher temperatures than other cells and was more resistant to electron and proton radiation.

Crystals of gadolinium-gallium-garnet were produced at the Bell Laboratories using a computer-controlled crystal-growing method.[3] In this method, a digital scale records the weight of the molten material from which the rare-earth garnet is drawn. The computer uses the change in weight of the molten metal to calculate the rate of change of the crystal weight, which provides an indication of the diameter of the crystal as it is formed. The gadolinium-gallium-garnet is used as a substitute material for magnetic bubbles, a new development by the Bell Laboratories, for information storage in electronic switching systems and in computers.

GEC-Marconi Electronics of Chelmsford, England, developed a compact, thin radar display screen based on a matrix of light-emitting gallium-arsenide-phosphide diodes.[4] The new screen is reported to be more functionally reliable and, because it uses less than 20% of the power of conventional cathode ray tubes, it runs at a much lower temperature.

[3] American Metal Market. Crystals of Gadolinium Produced at Bell Labs. V. 79, No. 176, Sept. 26, 1972, p. 11.

The RCA Laboratories in Princeton, N.J., produced the first instance of superconductivity of an alloy containing only two elements at a temperature higher than 20° K.[5] The new material, niobium-gallium, was superconductive at 20.3°K, which could reduce cooling costs for the superconductive phenomenon by 75% and could hasten practical applications in electric motors, generators, and transmission lines.

A patent was issued on the recovery of gallium values from circulating aluminate solution used in the Bayer process for producing alumina.[6]

The proceedings of a conference held at Pebble Beach, Calif., on optoelectronics were published by the Materials Research Corporation.[7] Papers on the technology of growing single crystals of gallium arsenide and gallium phosphide and the evaluation of optoelectronic materials were included in the proceedings.

Gem Stones

By Robert G. Clarke [1]

Although no formal gem stone mining industry exists in the United States, production in 1972 was estimated to be $2.7 million, an increase of 4% over the value of production in 1971. Individual collectors accounted for most of the quantity and value. Members of clubs in all States collected mineral specimens and rock samples. A few deposits were operated for the production of rough material that was sold directly to wholesale or retail outlets and sometimes to jewelry manufacturers.

DOMESTIC PRODUCTION

Gem stone production was estimated to be $1,000 or more for each of 38 States. The following States accounted for 77% of the total production, in thousands: Oregon, $793; California, $215; Arizona, $168; Texas, $163; Washington, $163; Wyoming, $142; Colorado, $131; Montana, $120; Nevada, $110; and Idaho, $105.

The State of Arkansas purchased the only diamond mine area in North America for development as a State park.[2] The property amounted to 867 acres, including the 78-acre diamond-producing crater. The cost was $750,000.

A find of semiprecious tourmaline was reported at the Vevel Pit on Plumbago Mountain, near Newry, Maine.[3] High value estimates were made for the find because of the large quantity of watermelon tourmalines, 3 inches in diameter, 4 to 5 inches long, green on the outside and pink inside.

The Ruggles mine, near Grafton, N.H., the oldest mica mine in the United States, was reopened to tourists and rock collectors on a fee basis.[4] The mine was originally opened in 1803 and was operated for the production of feldspar from 1932 to 1959. About 150 minerals have been found at the Ruggles mine. The list, in addition to mica and feldspar, includes amethyst, beryl, rose and smoky quartz, aquamarine, garnet, gummite, autunite, and zircon.

Tourists to the Mt. Washington Valley area of the White Mountain National Forest obtained collector's permits free of charge from the U.S. Forest Service Headquarters at Laconia, N.H.[5] The permit allowed hobby collecting only and required restoring work areas. Minerals mentioned as collected included smoky quartz, amethyst, topaz, feldspar, mica, and other pegmatite minerals.

Mines and minerals of the State of Virginia were described in a four-part series.[6]

A 10,000-pound boulder of jade was cut at the Majestic Jade Co., Riverton, Wyo.[7] The boulder was one of several removed by the company from its Verla-Irene operations near Jeffrey City, Wyo. After cutting, the jade sold for an average of $10 per pound.

Descriptions of field trips, events, and mineral and gem stone finds were reported throughout the year by Gems and Minerals, Lapidary Journal, Mineralogical Record, and Rocks and Minerals.

CONSUMPTION

Domestic gem stone output generally went to rock, mineral, and gem stone collections, objects of art, and jewelry. Apparent consumption of gem stones (domestic production plus imports minus exports and reexports) increased to $423 million, compared with $311 million in 1971, because of greater imports of diamond.

PRICES

During 1972, representative price ranges for first-quality, cut and polished, unmounted gem diamond were 0.25 carat, $100 to $400; 0.5 carat, $300 to $1,000; 1 carat, $700 to $3,500; 2 carats, $2,000 to $11,500; and 3 carats, $3,500 to $25,000. The median price for each range was 0.25 carat, $200; 0.5 carat, $550; 1 carat, $1,675; 2 carats, $4,500; and 3 carats, $9,000.

FOREIGN TRADE

Exports of all gem materials amounted to $184.9 million, and reexports, to $110.9 million. Diamond was 93% of the value of exports and 92% of the value of reexports. U.S. exports of diamond in 1972, on which work was done prior to reexport, amounted to 371,381 carats valued at $172.3 million. Of this, diamond, rough or uncut, suitable for gem stones, not classified by weight, was 345 carats valued at $18,975; cut but unset, not over 0.5 carat, was 63,780 carats valued at $11.5 million; and cut but unset, over 0.5 carat, was 307,256 carats valued at $160.8 million.

Reexports of diamond, on which no work was done, amounted to 1,430,244 carats valued at $101.9 million in categories as follows: Rough or uncut, suitable for gem stones, not classified by weight, 1,335,606 carats valued at $79.0 million; cut but unset, not over 0.5 carat, 40,384 carats valued at $7.7 million; cut but unset, over 0.5 carat, 54,254 carats valued at $15.2 million.

The six leading recipients of diamond exports and reexports accounted for 94% of the carats and 86% of the value and were as follows: Israel, 609,121 carats valued at $41.0 million; Belgium, 435,075 carats valued at $28.5 million; Switzerland, 203,209 carats valued at $37.7 million; Netherlands, 177,003 carats valued at $40.0 million; Japan, 154,497 carats valued at $34.7 million; and Hong Kong, 112,124 carats valued at $71.1 million.

Exports of all other gem materials amounted to $12.6 million. Of this total, pearls, natural and cultured, not set or strung, were valued at $0.2 million. Natural precious and semiprecious stones, unset, were valued at $9.7 million; synthetic or reconstructed stones, unset, were valued at $2.7 million. Reexports of all other gem materials amounted to $9.0 million. Reexports of pearls amounted to $0.3 million; of natural precious and semiprecious stones, unset, to $8.5 million; and of synthetic or reconstructed stones, unset, to $0.2 million.

Imports of gem material increased 36% in value compared with that of 1971. Diamond accounted for 88% of the total value of gem stone imports.

The four leading suppliers of diamond imports were as follows: United Kingdom, 1,334,000 carats valued at $182.2 million; Belgium-Luxembourg, 1,275,000 carats valued at $158.1 million; Republic of South Africa, 980,000 carats valued at $108.3 million; and Israel, 890,000 carats valued at $103.4 million.

Imports of emeralds increased 63% in quantity and 187% in value. Of 30 countries supplying natural emeralds to the United States, India furnished 276,198 carats valued at $6.2 million; Brazil, 90,483 carats valued at $1.5 million; and Colombia, 26,635 carats valued at $7.2 million. Also furnishing emeralds to the United States, but for which the country of origin was unknown, were Switzerland, 31,266 carats valued at $2.3 million; Hong Kong, 52,905 carats valued at $1.4 million; United Kingdom, 31,634 carats valued at $1.2 million; and France, 4,979 carats valued at $1.0 million. These seven countries furnished 90% of the quantity (in carats) and 94% of the value of total emerald imports.

Imports of rubies and sapphires increased 61% and came from 31 countries. Seven countries accounted for 95% of the value of rubies and sapphires, as follows: Thailand, $7.3 million; Sri Lanka (Ceylon), $1.5 million; Switzerland, $1.0 million; India, $1.0 million; Hong Kong, $0.7 million; France, $0.5 million; and United Kingdom, $0.5 million.

[1] Less than ½ unit.

cut but not set, and including others, amounted to $10.7 million in imports. From West Germany, the value of synthetics was $3.8 million; from Switzerland, $1.5 million; from France, $1.0 million; from Japan, $0.9 million; and from Austria, $0.8 million.

Marcasites, cut, not set, and suitable for jewelry were imported from two countries. From France, the value of marcasites was $77,000, and from Israel, $19,000.

Precious and semiprecious stones, rough and uncut, amounted to $6.2 million in imports. Three countries accounted for 75% of the value as follows: Colombia, $2.7 million; Brazil, $1.0 million; and Australia, $0.9 million.

Precious and semiprecious stones, cut but not set, amounted to $17.2 million in imports. Six countries accounted for 86% of the value as follows: Hong Kong, $7.8 million; Brazil, $2.2 million; Australia, $2.2 million; West Germany, $1.3 million; Japan, $0.9 million; and Taiwan, $0.5 million.

Natural pearls and parts imported from India were valued at $0.4 million. Other leading suppliers of natural pearls and the value of imports were as follows: France, $57,500; Hong Kong, $35,500; and Japan, $29,000. Imports of cultured pearls from Japan were valued at $7.3 million. Cultured pearls were also imported from Hong Kong valued at $112,600; from Burma, $89,000; and from Switzerland, $67,600.

Four countries accounted for nearly 100% of the value of imports of imitation pearls, as follows: Japan, $3.0 million; Hong Kong, $0.5 million; Taiwan, $0.2 million; and Spain, $0.04 million.

Of 18 countries supplying imitation gem stones to the United States, five countries accounted for 97% by value, as follows: Austria, $3.2 million; West Germany, $1.9 million; Czechoslovakia, $0.8 million; Japan, $0.4 million; and Hong Kong, $0.3 million.

WORLD REVIEW

Angola.—The consortium composed of Companhia de Diamantes de Angola (45%), De Beers Consolidated Mines, Ltd. (45%), and the Angolan Government (10%) reported the finding of two promising and extensive kimberlite deposits in its concession area.[8] No announcement of significant finds during the past year was made by the smaller companies.

Australia.—Australian production of natural sapphire was the world's largest in 1970.[9] Recovery of alluvial sapphires were mainly from Swanbrook Creek near Inverell and from Frazer Creek near Glen Innes, both in New South Wales. Dominion Mining, Ltd. commissioned a new $600,000 sapphire washing plant, claimed to be the world's largest. The sapphires ranged from colorless to dark blue, blue green, green, yellow, and blue yellow. A large portion of the marketable gems weighed more than 1 carat each, and some weighed as much as 40 carats.

Botswana.—The Orapa diamond mine, which became fully operational in June 1972, was the only producer of diamonds. It was estimated that 85% of the diamond production by weight was industrial diamond, and that 50% of the value was gem stone. About 8,540 tons per day were mined from the open pit. Little additional cost would be involved to expand processing by 50% should the market demand warrant the increase.[10]

Brazil.—Mineração Tejucana S.A. continued to be the largest diamond mining operation. The company operated two electric bucket dredges (12- and 9-cubic-foot buckets) on the Jequitinhonha River 54 miles north of Diamantina, Minas Gerais. The company also operated a suction dredge to remove barren sand ahead of the bucket dredges. Early in 1972, a large aquamarine weighing 65 kilograms was found near Ihla Grande, Municipio of Itaobim, Minas Gerais, and was the largest found in Minas Gerais since 1947.

Burma.—Burma's Eighth Annual Gem, Jade, and Pearl Emporium closed March 5, 1972, with reported sales of US$2.3 million, a 12% decrease from the previous year's record sales.[11] Jade was the biggest seller, accounting for US$1.7 million in sales. Several Burmese press accounts commented unfavorably on the status of the gem industry and suggested that a better system should be found. A ruby deposit was reported 60 miles northwest of Mogong, Kachin State.[12]

[10] Bureau of Mines. Diamond: Botswana. Mineral Trade Notes, v. 69, No. 9, September 1972, p. 3.

[11] Bureau of Mines. Gem Stones: Burma. Mineral Trade Notes, v. 69, No. 6, June 1972, p. 10.

Guyana.—M & V Diamond Mines was incorporated in Canada under a Dominion charter with the objective of mining diamonds in Guyana.[13] The company qualified in Guyana on December 31, 1971. The company obtained five diamond locations covering a combined length of 5.5 miles on th Potaro and Kopinang Rivers in the Mazaruni Mining District, the main diamond area of Guyana.

India.—All diamond production in 1972 was from the Panna District, Madhya Pradesh. Diamond mining operations were controlled and supervised by the Government of India-owned National Mineral Development Corporation (NMDC) in collaboration with the State Government of Madhya Pradesh. About 82% of the production was gem quality. NMDC imported mine-run diamond from African sources for cutting, polishing, and reexport, which in 1971 amounted to US$28 million as imports and US$42 million as exports.

Ivory Coast.—Diamond production was the only output of the mining industry in Ivory Coast since the stoppage of manganese ore mining in 1970.[14] Société Anonyme de Recherches et d'Exploitation Minières en Côte d'Ivoire (SAREMCI) produced 250,367 carats in 1971 and aimed for a similar production in 1972. Société Diamantifere de Côte d'Ivoire (SODIAMCI) stopped activities at Sassandra and at Seguela. On the other hand, the Waston Co. put into operation in January 1971 a processing plant that produced 65,382 carats in 1971 and for which the objective in 1972 was 72,000 carats.

Lesotho.—London and Rhodesian Mining and Land Co. (Lonrho) ceased prospecting operations at Kao in Butha Buthe district that it had begun in 1969 in a search for diamond.[15] Rio Tinto-Zinc Corp. (RTZ) pulled out of Letseng-la-Terai in the Mokhotlong district after more than 3 years of prospecting and sampling. Lonrho spent approximately $1.25 million and RTZ about $3.75 million on their respective operations. Newmont Mining Corp., which began prospecting at Kao in 1971, has spent $1.9 million on its operation.

Sierra Leone.—The "Star of Sierra Leone," a 969-carat diamond, third largest ever found in the world, was sold to Harry Winston, Inc., of New York for more than 900,000 pounds sterling or over $2 million. The sale of "The Star of Sierra Leone" contributed greatly to the profits of the National Diamond Mining Co. (DIMINCO). DIMINCO is 51% owned by the Government.[16] Diamond sales represented more than 60% of all Sierra Leone official exports in 1971. The importance of the diamond mining industry to the economy resulted in further prospecting for kimberlite sources by DIMINCO to offset projected decreases in production from alluvial areas.

South Africa, Republic of.—The Republic of South Africa and the Territory of South-West Africa combined are credited with over 40% of the gem-quality diamond output of the world in the period 1966 to 1971.[17] The De Beers group of mines, open pit, underground, and coastal, accounted for over 90% of the combined output of the two countries. De Beers developed a long-term mining plan for its mines under which part of the operations will be on standby to stretch out the lives of all the mines. Also, preference can be given to the sizes of diamond stones in demand by opening mines that satisfy the demand and by closing those that do not meet the demand.

United Kingdom.—A comprehensive list of sites in England was published for collectors of gem stones and ornamental rocks.[18] General locations for 18 mineral and rock types were shown on an accompanying map.

U.S.S.R. foreign trade organization specializing in diamond and jewelry exporting, exhibited amber products and diamonds at Unimart 1972, the Annual International Trade Fair, at Seattle, Wash.[19] Representatives of U.S.S.R. claimed that the production of diamond from Siberia equals that of the Republic of South Africa in quantity and quality. It was also claimed that the Kaliningrad amber fields are the largest in the world and constitute more than two-thirds of the world's amber reserve.

e Estimate. p Preliminary. r Revised.

[1] Total (gem plus industrial) diamond output of each country is actually reported except where indicated to be an estimate by footnote. In contrast, the detailed separate reporting of gem diamond and industrial diamond represents Bureau of Mines estimates in the case of all countries except Lesotho (all years), Liberia (1970 and 1971) and Venezuela (all years), where sources give both total output and detail. The estimated distribution of total output between gem and industrial diamond is conjectural in the case of a number of countries, based on unofficial information of varying reliability.

[2] Official estimate by Government of Guinea.

[3] Exports of diamond originating in Lesotho; excludes stones imported for cutting and subsequently reexported.

[4] Exports for year ended August 31 of that stated.

[5] Exports.

[6] All company output from the Republic of South Africa except for that from the Premier mines; also excludes company output from the Territory of South-West Africa and from Botswana.

TECHNOLOGY

A description of a technique to pan for diamond was published.[20] By a modification of the method used to pan for placer gold, it is possible to find diamond specimens in the United States. The specific gravity of gold is 19.3 in the pure state and may decrease to 15.0 with impurities. The specific gravity of diamond is 3.52. Hence, the difference between diamond and quartz or common sand, specific gravity of 2.7, indicates the care to be exercised in the panning operation for diamond. The technique was used by the author at localities in California. In addition, to these finds, Frank Fischer, an entrepreneur now of Lake Hamilton, Ark., applied his knowledge of diamond identification that he gained from 10 years experience in the diamond fields of Minas Gerais, Brazil, to sites south of Murfreesboro, Ark. Mr. Fischer reported diamond finds at several locations. He believed that the lack of familiarity with diamond by most collectors explains the dearth of diamond finds in the United States.

The quality of synthetic crystals was improved by application of computer controls to the growth process.[21] The system was developed for producing the rare-earth garnet (gadolinium gallium garnet or GGG) and can be adapted to growing other kinds of crystals.

At least 15 lasers were in use by diamond cutters around the world in New York, Antwerp, Israel, and India to increase the value of diamond gem stones by 100% or more.[22]

A yearlong scientific study of the patented 144-facet diamond cut showed that the new cut had an average brilliance 32.2% higher than that of the conventional 58-facet cut.[23]

The most valuable gem stone of the feldspars is moonstone. A complete description of the chemical and physical requirements for forming moonstone was presented in an article that also described means for proper identification.[24]

Gold

By J. M. West [1]

Free market gold prices rose sharply in 1972 as a result of monetary uncertainties, higher world industrial consumption, reduced supplies, and increased speculative buying of gold. The average price rose about $17 per troy ounce; the price change from the first of the year to the yearend was nearly $21 per ounce. On August 2, gold reached a record price, slightly over $70. The official price increased $3 per ounce to $38, effective May 8, 1972. U.S. official gold reserves declined 15.6 million ounces during 1972, owing mainly to transactions with the International Monetary Fund (IMF).

During 1972, domestic gold production declined to 1.45 million ounces, a drop of 3% from 1971 output. About 76% of the newly mined gold came from four producers: Homestake Mining Co., Kennecott Copper Corp., Carlin Gold Mining Co., and Cortez Gold Mines. Domestic consumption of gold rose 5% to 7.3 million ounces, with jewelry and arts accounting for 60% of the total consumed. Net imports declined 21% and industry stocks rose approximately 1% during the year.

World gold production declined in 1972, chiefly because of a continuing drop in the Republic of South Africa production. The Republic of South Africa supplied 65% of the world's newly mined production; the

[3] U.S. Department of the Treasury. Convertible to ounces at official price of $35 per ounce through 1971 and $38 per ounce in 1972.

U.S.S.R. ranked second to the Republic of South Africa, with an estimated 6.9 million ounces produced in 1972. Third and fourth were Canada and the United States, both with declining outputs.

David Lloyd-Jacob, Manager, Consolidated Gold Fields Ltd., told a conference in London in October 1972 that he estimated the total newly mined world supply of gold coming to markets in 1972, including that from the Republic of South Africa and Russian sales, would decline 5.1 million ounces to 38.6 million ounces. Of the total, it was estimated that 16.1 million ounces would go to jewelry manufacturers in advanced countries, 11.9 million ounces-sharply lower than in 1971 to jewelry manufacturers in less developed countries, and the balance into other fabrication including coins. Substantial net dishoarding of gold was anticipated to supply rising industrial demands in 1972–73. Russian sales of gold on world markets have been estimated at 8 million ounces in 1972 and were expected to drop to 4.8 million ounces in 1973. R. C. J. Goode, President, Chamber of Mines of South Africa, predicted in an address at the same London conference that even with an immediate increase in the official gold price to $70 per ounce the Republic of South Africa production would probably decline to 26.3 million ounces by 1982. If the price was to go to $100, a 1982 output of 27.2 million ounces was predicted. Estimates took into account various factors, such as working costs, pay limits, ore reserves, etc.

Legislation and Government Programs.—Following the December 18, 1971, accord of finance ministers from 10 leading industrial nations at the Smithsonian Institution, Washington, D.C., the U.S. Congress passed a bill which was signed into law March 31, 1972, (Public Law 92–268) to devalue the dollar to the equivalent of $38 per troy ounce of gold. In early May, $1.6 billion was appropriated to adjust U.S. balances in international financial institutions to accomodate the devaluation, and on May 8, 1972, the Act became effective, changing the par value of the dollar to one thirty-eighth of an ounce of gold. A number of bills were introduced in the Congress to permit American citizens to hold gold but none of the bills reached a vote.

In a report issued November 18, 1972, by the Subcommittee on International Exchange and Payments of the Joint Economic Committee, Congress of the United States (92d Congress, 2d Session), the following recommendations were made in respect to actions on gold for the purpose of deemphasizing gold as a reserve asset:

> 1. The March 1968 two-tier gold agreement should be modified to permit, at their own initiative and volition, sales of gold in the free market by the IMF and central banks. On the other hand, the prohibition against central bank purchases of gold in the free market or directly from the Republic of South Africa ought to be maintained.
> 2. Under a reformed international monetary regime, special drawing rights should be made acceptable in lieu of gold in all transactions between the IMF and its member countries.
> 3. As soon as the international monetary reform that is currently being negotiated is achieved, all prohibitions on the purchases, sale, and holding of gold by American citizens should be promptly abolished.
> 4. The current agreement committing the IMF to purchase gold from the Republic of South Africa under certain conditions ought not to be renewed. Instead it should be terminated in 2 years when it expires. Recommendations were also made toward strengthening the special drawing rights mechanism.

A Canadian exchange opened at Winnipeg in November for trading gold futures, and because of many questions, the Treasury Gold Regulations permitting persons and firms licensed by the Treasury Department to buy and hold gold for commercial, industrial, and artistic purposes "in amounts necessary to conduct their business operations" were clarified, as follows: Under the Regulations, the purchase of gold in futures markets is treated in the same manner as other gold purchases:

> 1) Treasury's Gold Regulations provide that Americans may not acquire any interest in gold, at home or abroad, unless authorized by a Treasury license. This prohibition is applicable to U.S. citizens wherever residing, to noncitizens residing in the United States and to U.S. companies and their foreign subsidiaries.
> 2) U.S. firms and individuals authorized by a Treasury license to buy or hold gold for commercial, industrial, and

artistic purposes may engage in gold futures transactions only to an extent consistent with their licenses. Specifically, purchases of gold futures are limited in amount to the specific inventory restrictions contained in their licenses and the transactions must serve the legitimate and customary purposes of their businesses. Speculative activities by gold licensees not related to current business operations could result in the revocation of their gold licenses and subject them to the civil and criminal provisions prescribed by law.

Gold purchased for future delivery will be included in the authorized inventory of the gold licensee. Gold licensees are required to set forth their net futures position in their regular reports to the Treasury Department and their position is subject to inspection at all times.

3) U.S. firms and foreign subsidiaries of U.S. firms which are members of commodity exchanges abroad may engage in brokerage activities on such exchanges for Treasury gold licensees and for firms and individuals not subject to the jurisdiction of the United States. A Treasury gold license is not required for brokerage functions.

At the same time, brokerage firms may not acquire any interest in gold for their own account for present or future delivery. Brokerage firms engaging in brokerage activities must take reasonable measures to assure that the transactions on behalf of U.S. gold licensees serve legitimate business purposes and are consistent with the limitations contained in the gold license. They must also take reasonable measures to assure that non-U.S. citizens with whom they transact business are not acting on behalf of U.S. citizens.

The Office of Minerals Exploration (OME), U.S. Geological Survey continued its program of offering participatory loans for gold exploration up to 75% of approved costs. However, only a few relatively small loans or active contracts were approved or in effect.

DOMESTIC PRODUCTION

A decline in domestic gold production in 1972 was largely the result of a strike at the Homestake gold mine, Lead, S.D., which together with other production problems cut over 100,000 ounces from the Homestake's output. Outputs from copper mining States of Nevada, Arizona, New Mexico, and Montana, were generally higher in 1972, offsetting part of the South Dakota drop; Colorado production increased owing to greater base-and-precious-metal mine activity. A decline in Utah output was signalled by the yearend closure of the Mayflower mine, operated under lease by the Hecla Mining Co. In 1972 the Mayflower produced 46,863 ounces of gold in addition to other metals. Downtrends continued in most other States, although there was a widespread increase in prospecting and exploration activity because of higher gold prices. Golden Cycle Corp. announced a $6 million program to reactivate its mining operations in the Cripple Creek area of Colorado. Work was begun by a subsidiary, Cripple Creek Gold Corp., to rehabilitate the Carlton tunnel and rebuild mill facilities. Diamond drilling was planned in 1973 on the 3,111-foot level, reached from the Ajax shaft which was also rehabilitated. The Shenandoah mill of Standard Metals Corp., in the Silverton area, San Juan County, Colo., treated about 700 tons of ore daily from the Sunnyside mine.

In Alaska, a gold dredge which had been inactive for two seasons, was reactivated on the Solomon River, in the Nome area, and offshore gold deposits were under investigation for possible new oceangoing dredge operations at several locations. UV Industries, Inc. (formerly United States Smelting, Refining and Mining Co.) operated a gold dredge at Hogatza, in the Yukon River region. Other smaller scale placer mining was active in the Hot Springs, Fortymile, Ruby, and Iditarod districts of Alaska. In Montana, Judith Gold Corp. continued evaluation of its property in the Kendall district near Lewistown, Fergus County. Gold milling facilities were under construction in Nevada at Silver Peak, Esmeralda County; at a property near Manhattan, Nye County; and at a site near Tonopah, Esmeralda County.

Gold production dropped 21% to 407,397 ounces valued at $23.1 million in 1972 at the Homestake mine in South Dakota. Ore grade averaged 0.278 ounce of gold per ton treated compared with 0.285 ounce in 1971.

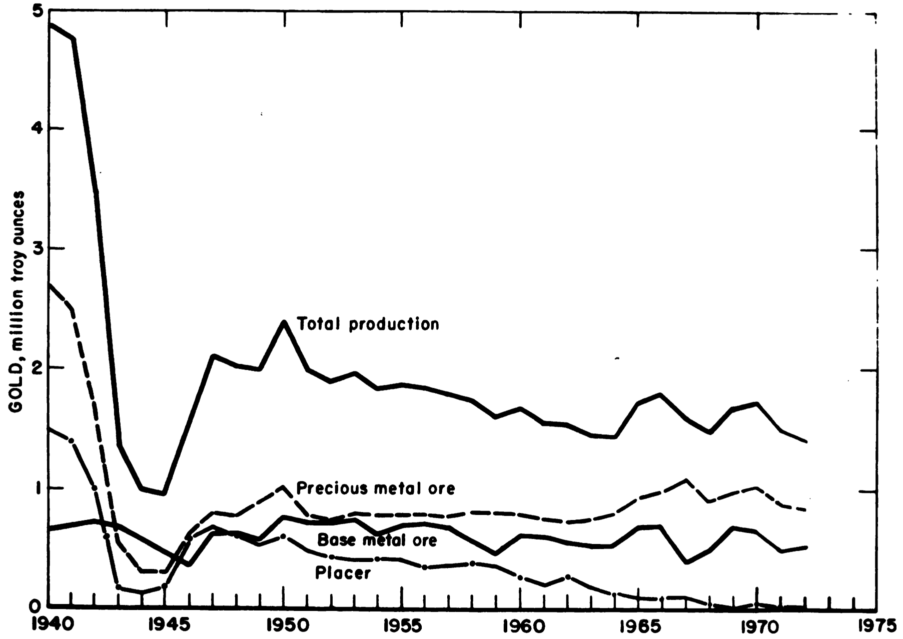

Figure 1.—Gold production in the United States.

A total of 1.47 milion tons of ore was milled. Construction of a new gold recovery unit using a "charcoal-in-pulp" process was nearly completed and was due to go into operation in early 1973. Lower gold losses were anticipated in 1973 as a result. Measured ore reserves at the Homestake mine were estimated at 7.3 million tons averaging 0.299 ounce per ton at the end of 1972. Deep level development reached the maximum project depth, shaft equipment was installed, and new working levels were driven in preparation for increased extraction rates.

At the Cortez mine, Lander County, Nev., mill throughput rose to 803,000 tons in 1972; however, the mine was due to close in early 1973 owing to ore depletion. Production increased 59% to 190,600 ounces compared with 120,251 ounces produced in 1971. The average grade milled was 0.214 ounce per ton and 88.9% was recovered. A large low-grade waste dump, containing 1.6 million tons of mine-run material, was constructed for cyanide "heap-leaching" and during the year 37,600 ounces was produced by this low cost method. Material in the waste dump was estimated to average only about 0.06 ounce per ton and ultimate extraction was expected to be 50% or higher. Cortez Gold Mines also conducted studies in the nearby Gold Acres area and planned to establish a heap-leach/activated carbon extraction operation there, trucking any quantities of milling grade ores found to the Cortez mill for treatment.

The Carlin mine, Eureka County, Nev., produced 194,000 ounces of gold compared with 199,000 ounces in 1971. Sales were valued at $11.7 million compared with $8.3 million in 1971. The average grade of ore milled was 0.238 ounce per ton, compared with 0.287 ounce per ton in 1971. Heap-leaching was credited with recovery of about 2% of the gold, with the balance from treating better grade oxidized and carbonaceous ores in the established milling circuits. Investigations and production planning continued at the Bootstrap deposit, which was expected to be partly a heap-leach operation, with the better ores hauled to the Carlin cyanide plant for processing. Another deposit nearby, the Blue Star, was also scheduled for development. Ore reserves at the main Carlin deposit were estimated at yearend to be 2.71 million tons averaging 0.317 ounce per ton.

This compared with 3.5 million tons averaging 0.297 ounce per ton at yearend 1971. Combined reserves at the Bootstrap and Blue Star deposits were estimated at 1.1 million tons of somewhat lower grade ore. Production was scheduled at the latter two deposits about yearend 1973. Carbon-column gold extraction units underwent testing at each major gold operation (Homestake, Cortez, and Carlin) and were expected to lead to more efficient production.

At Bingham, Utah, the Utah Copper Division, Kennecott Copper Corp., remained the principal byproduct gold producer, reported gold production, mostly from the Bingham pit totaling 350,080 ounces in 1972. The Knob Hill gold mine, operated in conjunction with the Gold Dollar property of Day Mines, Inc., in the Republic district of northeastern Washington, was a continuing source of gold; reserves reportedly were adequate for about 2 more years of operation. Day Mines' share of production from the Gold Dollar Lease was 15,281 tons of ore milled averaging 0.85 ounce of gold and 2.34 ounces of silver per ton. The firm's share in output from a joint operation with Knob Hill Mines, Inc., was 12,255 tons of ore averaging 0.43 ounce of gold and 2.5 ounces of silver per ton. An $80,000 diamond drilling program was scheduled in 1973 to develop further reserves.

Production from the Mayflower mine, located in the Park City district of Utah and leased from Newpark Resources, Inc. by Hecla Mining Co., included 46,863 ounces of gold. Accompanying the gold were 620,024 ounces of silver, 3,586 tons of lead, 2,163 tons of zinc, and 1,495 tons of copper. A total of 114,604 tons of ore was produced. At yearend, Hecla terminated its lease, owing to depleted ore reserves, and closed the mine.

All but a few thousand ounces of Colorado's gold production in 1972 came from the Sunnyside mine, operated by Standard Metals Corp.; the Idarado mine, operated by Idarado Mining Co.; and the Leadville mine, operated by American Smelting & Refining Co. The latter mines were operated primarily for base metals, with the gold as a byproduct.

Of total U.S. gold production, the leading four producers, Homestake Mining, Kennecott Copper, Carlin Gold Mining, and Cortez Gold Mines, contributed 76%; 98% of the total was accountable to 25 leading producers (table 6). Placer and byproduct gold production accounted for 1% and 4%, respectively, of total gold output. An estimated 2.1 million ounces of secondary gold was produced compared with 2.2 million ounces in 1971.

CONSUMPTION AND USES

Domestic consumption of gold, as reported by the Office of Domestic Gold and Silver Operations, U.S. Department of the Treasury, rose 5% to 7.3 million ounces in 1972. Consumption in 1972, as indicated by reports of fabricators of industrial and other products, was divided, as follows, in thousand ounces (with 1971 figures for comparison): Jewelry and arts, 4,344 (4,299); dental, 750 (750); and industrial, including space and defense 2,191 (1,884). Increases in most categories were the result of an upsurge in the U.S. economy and greater affluence.

Consumption was undeterred by sharply higher gold prices, although manufacturers noted increasing efforts to substitute other metals, use thinner plating, cover smaller areas of products, and lower the carat content of gold. Most users were reported "by choice or by lack of a suitable substitute, to be sticking with gold and the higher costs involved."[2] Increased costs were passed on to consumers of many products, notably jewelry purchasers, but for a variety of reasons some manufacturers had to absorb the increases themselves. Electronic products makers were particularly hard pressed because of intense competition and were reported investing in more spot-plating and selective plating equipment in 1972.[3] Palladium was used more in contact and connector points as a base for reducing the thickness of gold. Some increase in substitution of tin for gold was noted in the manufacture of printed circuit boards.

[2] Wall Street Journal. Guessing About Gold: Metal's Unsettled Price Confuses Firms; Some Hold Off Buying, Others Build Stocks. V. 180, No. 113, June 12, 1972, p. 34.

[3] Snyderman, Nat. Price Pressures May Hit Gold Vendors to Electronics Firms. Am. Metal Market, v. 79, No. 156, Aug. 28, 1972, p. 61.

One firm offered a new customer's service to solve technical problems with contact bimetal materials.[4] Other firms sent technical representatives to plating plants to advise customers on ways to economize on use of gold. It was contended that gold plating operators lost from 10% to 60% of their gold because of inefficiencies.[5] A new form of gold salts to provide more uniform gold plating was said to have been developed.[6] A superior doped gold ribbon and wire product was developed,[7] and a gold-coated foil was used in an experimental telephone needing no metal contacts for dialing.[8] A substitute dental alloy using titanium or chrome base alloys instead of gold was marketed,[9] and gold-plated beryllium-copper radar waveguides were used in the new Hawk missile.[10]

STOCKS

Monetary.—Official U.S. gold stocks, including those in the Exchange Stabilization Fund, were valued at $10,487 million based on $38 per ounce gold at the end of 1972 compared with $10,206 million based on $35 per ounce gold at the end of 1971. The equivalent amounts of gold were 276.0 million ounces at the end of 1972 compared with 291.6 million ounces a year earlier for a net outflow of 15.6 million ounces. Virtually all of the outflow was the result of a resale of gold to the IMF in the early part of the year. Suspension of convertibility of dollars to gold, begun in August 1971, remained in effect at yearend 1972.

Federal Reserve Banks held $15,530 million (408.7 million ounces at $38 per ounce) worth of "earmarked" gold at the end of 1972 for foreign and international agency accounts. This compared with $13,815 million (394.7 million ounces at $35 per ounce) at the end of 1971. Total gold stocks of national monetary authorities and international institutions (excluding the U.S.S.R., other Eastern European countries, and the People's Republic of China) were valued at an estimated $45,000 million at the end of 1972 compared with $44,742 a year earlier. Stocks were equivalent to about 1,184 million troy ounces compared with 1,177 million ounces at yearend 1971, indicating an accumulation of nearly 7 million ounces.

World monetary gold stocks at the end of 1972 were distributed, as follows, in million ounces: United States (276.0); IMF (153.3); West Germany (117.3); France (100.6); Switzerland (83.1); Italy (82.3); the Netherlands (54.2); Belgium (43.1); Portugal (26.9); Canada (21.9); Japan (21.1); Republic of South Africa (17.9 compared with 10.8 at end of 1971); Spain (14.2); Venezuela (11.2); Bank for International Settlements (5.7); and others (155.2). The largest gain in stocks was with the IMF, which acquired about 18.2 million ounces, mainly from the United States, as a result of dollar devaluation. "Paper gold" Special Drawing Rights (SDR's) in the IMF totaled 9,431 million at the end of 1972 compared with 6,378 million at the end of 1971, an increase of 3,053 million. The SDR's, created to increase world money liquidity, were the official equivalent of 269.5 million ounces of gold (the unit of SDR by definition is equivalent to 0.888671 gram of fine gold). Thus, SDR's added to amounts in existence at yearend 1971 were equivalent to 87.2 million ounces of gold, over twice the free-world mine production of gold during 1972.

Industrial.—Inventories of gold at domestic refiners and fabricators rose approximately 1% during 1972, to 4.41 million ounces, according to data collected by the Office of Domestic Gold and Silver Operations.

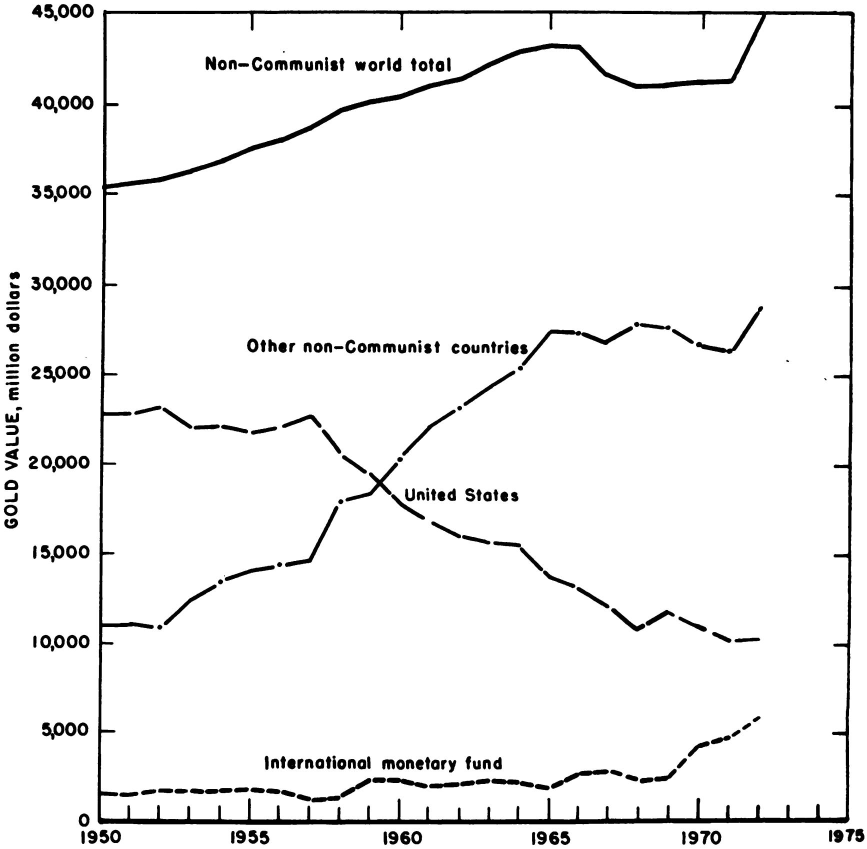

Figure 2.—Gold reserves of free world central banks and governments.

PRICES

Free market gold prices rose to new highs during the year, reaching $70.45 per troy ounce (Engelhard Industries selling price) on August 2. This contrasted sharply with the official U.S. price of gold which was formally increased from $35 to $38 per ounce on May 8, and continued through the balance of the year at that level. The lowest free market price of the year was on January 3, the first trading day when the selling price was $44.45 per ounce. The price on the last trading day, December 28, was $65.10, an increase of $20.65 or 46% for the year. The average price for the year, $58.60 per ounce, was 42% higher than in 1971. High prices generally were attributed to speculative demand due to unsettled monetary and trade problems, also a restricted supply of newly mined gold coming to market.

Table 3.—U.S. monthly gold selling prices, per ounce

(Engelhard Industries)

Month	1972		
	Average	Low	High
January	$46.20	$44.45	$47.80
February	48.70	47.45	49.70
March	48.78	48.50	48.90
April	49.46	48.75	50.20
May	55.09	50.80	59.90
June	62.54	59.65	65.30
July	66.15	65.30	68.75
August	67.49	65.60	70.45
September	65.85	61.70	67.70
October	65.32	64.55	65.95
November	63.36	60.80	64.60
December	64.31	63.35	65.85
Year total	58.60	44.45	70.45

FOREIGN TRADE

Exports of gold in 1972 went largely to Switzerland (40%), the Netherlands (25%), and Canada (16%), with the balance to eight other countries. Scrap comprised 18% of the exports, going to the United Kingdom (45%), Belgium-Luxembourg (40%), and four other countries. A small quantity of monetary gold was included in bullion exports.

Net imports of gold, mostly as bullion, showed a sharp rise (fig. 3) compared with those of 1971 and totaled 4.65 million ounces. The inflow of gold in ore, scrap, and base bullion was balanced by an equal outflow in the form of scrap. Total imports of 6.13 million ounces were valued at $357.7 million; total exports of 1.47 million ounces were valued at $63.1 million. The bulk of the imports came from Canada (49%), Switzerland (33%), and the U.S.S.R. (9%). The balance was from 23 other countries. Virtually all imported gold was destined for industrial use.

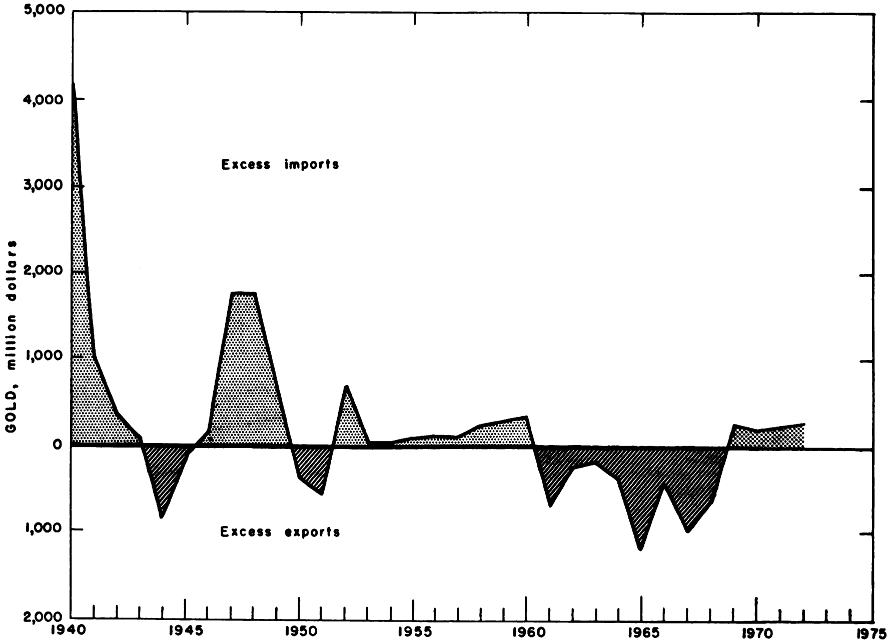

Figure 3.—Net exports or imports of gold.

WORLD REVIEW

World gold production declined again in 1972 to 44.7 million ounces, a drop of 4%. Outputs of most of the main producing countries were lower except in the U.S.S.R. where the Government heavily subsidized production. Policies of the Republic of South Africa limiting the sale of gold continued to exert a dominant influence on the gold markets, although releases of Soviet gold had significant effects in offsetting the shortfall in world supply. World monetary unrest and trade problems resulted in rising speculative demands for gold and higher world prices as supplies fluctuated. Shipments of gold from the Republic of South Africa to the United Kingdom were only about 55% of those in 1971 indicating a diversion to other markets, primarily Switzerland. United Kingdom shipments of gold to the Far East and Middle East were sharply lower showing resistance on the part of purchasers in those areas to high world prices. World industrial consumption was estimated at 4 to 5% higher than in 1971, consonant with the expanding economies of major manufacturing nations.

Argentina.—Corporación Andina S.A., reported discovery of a placer gold deposit near the El Condor mine in Jujuy Province. The company sought assistance to develop the property under claim.

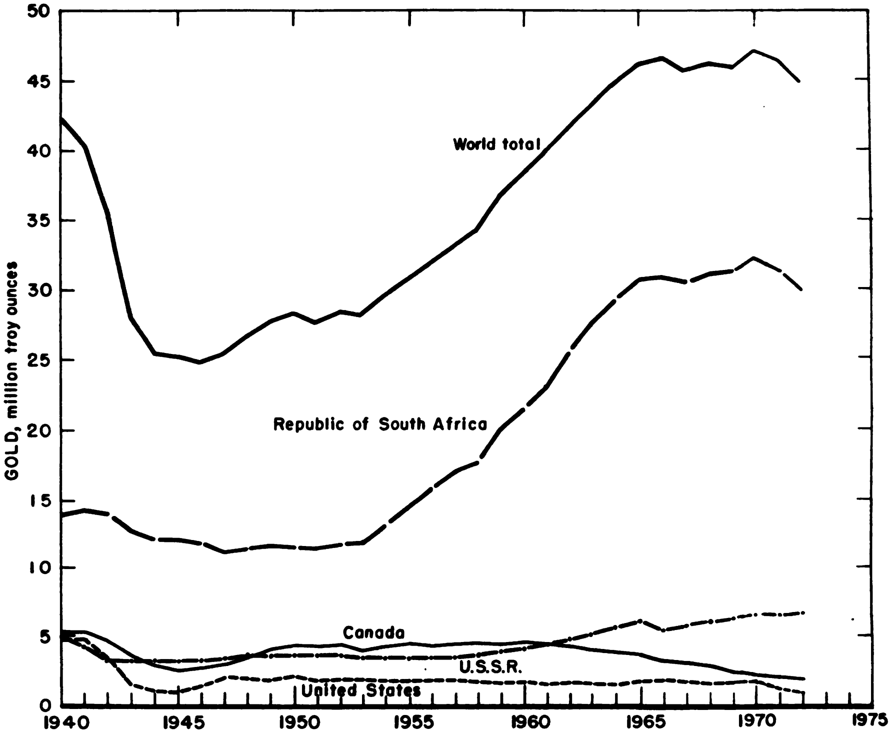

Figure 4.—World production of gold.

Australia.—Australian refinery production of gold from ores and concentrates consisted of 540,300 ounces from domestic and 112,220 ounces from foreign sources. Also, 20,800 ounces was produced from domestic scrap and 2,100 ounces from foreign scrap. Mine production was up 12% compared with that in 1971.

Federal subsidies under the Gold Mining Industry Assistance Act were increased 50% to A$12 maximum per ounce (A$1 = US$1.275); also, producers were allowed to keep 50% instead of 25% of the difference between the free market and official prices of gold. Most Australian and New Guinean gold was marketed. as before, through the 700-member Australian Gold Producers' Association, a cooperative organization of producers. As a result of higher gold prices, additional development work was planned at a number of mines, including the Lake View and Star mines, the largest remaining operations in the Kalgoorlie district of Western Australia. Exploration of a gold-bearing structure was continued near Bathurst, New South Wales, by Pacific Copper Mines Ltd. Gold was reported associated with vanadium in a deposit being explored by Ferrovanadium Corp. at Barambie, east of Geraldton, Western Australia.

Bolivia.—The Bolivian Government issued a Supreme Decree in June 1972 reducing royalties on gold production payable to the Government for the purpose of encouraging gold mining, especially of placer deposits north and northeast of La

Paz.[11] Then, in December the Government issued another Decree annulling the one in June.[12] The new Decree eliminated royalties altogether but applied a 2% tax on gross value of gold production to amortize debts owed by the Gold Cooperatives to the Banco Minero and Bolivian Development Corporation. South American Placers Inc., remained active in Bolivia, selling 11,310 ounces produced in unrefined form in the first half of 1972. Gaensel Gold Mines & Co. completed a shaft to explore placer material on the upper Tipuani River and arranged with Lipez Mining Co. to exploit a placer deposit near the village of Mojotoro. The firm also was expected to take over the placer operation of Condor Mining Co., which had been active since about 1967.

Brazil.—Lode gold production came from one group of mines operated by Mineração Morro Velho S.A. in the area of Nova Lima, Minas Gerais. Output was 5% more than in 1971 when 157,400 ounces was recovered together with silver and white arsenic from 529,218 short tons of ore. Battelle Memorial Institute was preparing plans to modernize the plant, expanding arsenic output and adding sulfur recovery equipment. Cia.Mina da Passagem operated two floating dragline gold washing plants near Mariana, Minas Gerais. About 6,400 ounces was produced in 1971 at this operation. Mineração Tejucana S.A. recovered 2,600 ounces (also 1971) during diamond dredging on the Rio Jequitinhonha, Minas Gerais. A small quantity of byproduct gold was recovered from lead refining at the Panelas smelter, Paraná. A number of small-scale hand and portable washing plant operations in various parts of Brazil supplied the balance of production.[13]

Canada.—Canadian gold production continued its long decline with a 7% drop in 1972. Ontario remained the largest gold producing Province, followed by Quebec, the Northwest Territories, and British Columbia. The greatest drops in production were in Quebec (17%), and Ontario (11%). Significant increases were noted in British Columbia (48%), the Prairie Provinces (49%) and the Atlantic Provinces (100%). Total output was divided approximately, as follows, in percent: Ontario (49); Quebec (27); Northwest Territories (14); British Columbia (6); Prairie Provinces (3); Atlantic Provinces (1); and the Yukon Territory (0.3). In Quebec five gold mines treated 2.4 million tons of ore and shipped products containing 359,469 ounces of gold valued at $13.3 million in 1972. The balance of production was from about 15 base metal mines reporting 12.25 million tons of ore treated and shipments of 181,631 ounces of gold valued at $6.7 million. It was announced about midyear that the Canadian Government would extend its Emergency Gold Mining Assistance Act another 3 years until June 30, 1976. Under the act, gold producers were assured a return of Can $48.27 per troy ounce on mine production.

During the year, Falconbridge Nickel Mines Ltd. announced plans to bring into production a section of its Ellis Lake Opemiska property in the Chibougamau area of Quebec where high copper-gold values were found. A 300-ton-per-day mill addition was planned for treatment, and ore reserves were estimated about 0.5 million tons. Teck Corp. continued the operation of its Lamaque mine in Quebec, which had been scheduled for closure. Also, because of rising gold prices, East Malartic Mines Ltd. was scheduled to remain in operation. Agnico-Eagle Mines Ltd. prepared to open its Eagle gold mine in the Joutel area of Quebec and scheduled startup of a $3.8 million 1,000-ton-per-day mill in 1973. Chibex Ltd. planned to develop a gold-copper property in Rohault Township, in the Southern Chibougamau area. In Ontario, Dickenson Mines Ltd. drifted into some rich gold ore in a section purchased from Robin Red Lake Mines Ltd. and expanded milling to 450 tons per day. Campbell Red Lake Mines Ltd. reported about the same rate of production in early 1972 as the year before with recovery of 0.65 ounce of gold per ton of ore milled. Earnings were sharply higher because of rising gold prices. The firm will spend $1 million to control emissions at its roaster plant in 1973. Pamour Porcupine Mines Ltd. was expanding capacity from 1,900 to 2,500 tons of ore per day in the Porcupine district of Ontario and in November 1972 acquired Aunor

[11] U.S. Embassy, La Paz, Bolivia. State Department Airgram A-155, July 7, 1972, 7 pp.

[12] ———. State Department Airgram A-308, Dec. 8, 1972, 3 pp.

[13] U.S. Embassy, Rio de Janeiro, Brazil. State Department Airgram A-236, Oct. 10, 1972, pp. 19, 20.

Gold Mines Ltd. Pamour milled 346,700 tons of ore grading 0.152 ounce per ton in the first half of 1972. Kennco Explorations Ltd., owned by Kennecott Copper Corp., reported a gold-silver discovery in the Toodoggone River area north of Smithers, British Columbia and held about 600 claims. Other companies were also active in the area.

Colombia.—Pato Consolidated Gold Dredging Ltd., 67.5% owned by International Mining Corp., reported 1971 production of 60,910 fine ounces of gold from 17.8 million cubic yards of gravel. The firm operated four dredges, two of which were moved during the year to new locations. Reserves declined to about 242 million cubic yards averaging 13.1 cents per yard and an additional 167 million yards averaging 10.1 cents per yard (basis $38 per ounce).

Costa Rica.—Financing of a new gold and silver development project was considered by the U.S. Export-Import Bank. The Costa Rican Government continued to require that all gold production be sold to the Central Bank at the official monetary rate.

Dominican Republic.—New York & Honduras Rosario Mining Co. (name changed to Rosario Resources Corp. in 1973) and J. R. Simplot Co., in a joint venture, continued exploration at the Pueblo Viejo gold-silver mine and planned to go into production in late 1974, processing 6,000 tons of oxidized ores per day. At yearend reserves were estimated at about 20 million tons averaging 0.15 ounce of gold and 0.76 ounce of silver. In addition, an equally large underlying sulfide zone was reported to contain 2.19% zinc, 0.25% copper, 0.131 ounce per ton of gold and 1.12 ounces per ton of silver, and a pilot plant was planned for test processing of this ore.

Fiji.—Fiji's gold production, all from the Emperor Gold Mining Co. mine, was sold on the commercial market and in 1971 brought in $3.5 million in foreign exchange. Because of the mine's importance to the local economy, the Government decided to subsidize the operation to the extent of $750,000 for further exploration and development work.

India.—Bharat Gold Mines Ltd. was established to explore and develop the Ramgiri gold field in the Anantapur district of Andhra Pradesh. The Kolar mines in Mysore continued to provide the bulk of Indian gold production under severe problems of depth, heat, and difficult ground control. Most of the balance of production came from the Hutti mines, also in Mysore. Domestic commercial consumption of gold was probably slightly higher than the 48,000 ounces reported in 1971.

Japan.—Domestic consumption of gold during the fiscal year beginning April 1, 1972, was estimated at about 2.8 million ounces. A 13% increase was forecast for the 1973 fiscal year beginning April 1, 1973. Effective on that date, restrictions on importing gold into Japan were to be lifted as a move toward further import liberalization.

Mexico.—Industrias Peñoles, S.A. and affiliates accounted for about 70% of Mexican gold production in 1972. Mexican output was largely byproduct from base metal mining. During 1972, about 32,200 ounces came from gold-silver ores and concentrates; 42,800 ounces came from copper refining, with the balance from other sources, including a small quantity from placer operations. Mid-Continent Mining Corp. (U.S.) announced plans to develop a large gold placer operation in southern Mexico.

New Zealand.—South Westland Minerals Ltd. announced plans to operate two small gold dredges in the Gorge River area of the West Coast where the firm had a 63,000-acre claim. Output of about 12 ounces per day was expected.

Papua-New Guinea, Territory of.—New Guinea Goldfields, Ltd. reported gold bullion sales valued at $485,191 and gold premium receipts at $109,283 in 1971 and values were expected to be higher in 1972. Exploration began on gold leases in Wau under an agreement with C.R.A. Exploration Pty. Ltd. Byproduct gold production began from the copper operation of Bougainville Copper Pty. Ltd. on Bougainville Island. Highland Gold Development NL began construction of a 100-ton-per-day mill at its Kathnel gold deposit near Kainantu, New Guinea.

Peru.—Production included about 34,100 ounces in refined form. About 2,300 ounces of placer gold was produced in 1972. A commission was appointed by the Government of Peru to study and recommend measures to increase Peruvian gold production. Banco Minero reportedly discovered a rich gold placer area on the Inambari River in the Department of Madre de Dios, and small scale production was started. Another gold deposit was under study in the Rioja area of northern Peru. Peru's gold consumption was reportedly about 200,000 ounces annually, more than twice the production.

Philippines.—Production decreased in 1972, mainly because of less byproduct gold output from copper operations. A complex subsidy system remained in effect.[14] Benguet Consolidated Inc. remained the only important lode-gold mining firm in the Philippines, contributing about one-fifth of total gold production.

Rhodesia, Southern.—Efforts were underway to expand gold production with the reactivation of the Shamva mine, once a significant producer. The Dalny mine remained the country's largest gold producer in 1972.

South Africa, Republic of.—Production declined for the second straight year, dropping 7% to 29.2 million ounces in 1972. During the first 9 months of 1972, mines in the Transvaal area produced 14.24 million ounces; 7.85 million ounces was produced in the Orange Free State area. The balance of production came from Cape Province (3,760 ounces) and Natal (965 ounces). The largest and richest gold producer in 1972, as before, was the West Driefontein mine with 2.42 million ounces and mill recovery of 0.96 ounce of gold per metric ton of ore treated. The second largest output was recorded by Vaal Reefs, with 2.12 million ounces produced and recovery grade of 0.40 ounce per ton. Ten other mines produced over 1 million ounces each in 1972.

Generally, during 1972 larger tonnages of lower grade ores were mined because higher gold prices permitted economical production at a lower cutoff grade. Such procedures tend to prolong the productive life of a mine and, in fact, are required by the Republic of South Africa law as a conservation practice. Output from the Rand Refinery Ltd. plant at Germiston, during the company's fiscal year, October 1, 1971, to September 30, 1972, was 30,140,490 fine ounces of gold and 3,295,170 fine ounces of silver. Most of this was from bullion received from the mines, but 98,925 ounces of gold and 473,837 ounces of silver were from scrap. Several mine fires during the year caused production losses and a variety of accidents brought the gold mining fatality rate to about one every 48 hours. Mining costs rose, partly as a result of basic wage increases and devaluation which made imported materials and machinery more expensive. Nearly one-fourth of all production in 1972 went into official reserves of the Republic of South Africa Reserve Bank and, thus, was not available to the free market. The Bank reported gold reserves equivalent to 11.54 million ounces in January, rising to 17.53 million ounces in October (converted at the rate of R28.30 per troy ounce), and accumulation continued through the yearend.

U.S.S.R.—Gold production was higher in 1972, with intensified activities in all producing areas but particularly in the desert areas of Kazakhstan and Uzbekistan, south of the Ural Mountains, and in the region of the Aral Sea. An important new discovery was reported in the Mugodzhar Mountains of western Kazakhstan, and large scale gold production was planned to begin about 1975. Development continued at the Muruntau gold field, on the south slope of the Muruntau Mountains in the central part of western Uzbekistan. A large cyanide/ion exchange extraction plant was in operation and open pit/underground mine development was in progress at Muruntau. Soviet gold sales on world markets rose sharply in 1972 as a result of the need for foreign exchange, principally to purchase wheat.

Venezuela.—Canadian firms, Fairway Explorations and Nor-Acme Gold Mines, sampled a placer gold area in the eastern part of the State of Bolívar and reported relatively high grade assay returns. More extensive sampling was planned in 1972–73. Ores containing disseminated submicroscopic gold from the Callao region of Venezuela were investigated by engineers of the Evaluation Center of the Ministry of Mines, and comparisons were made with Nevada (U.S.) deposits.

TECHNOLOGY

Research to apply cyanide heap-leaching and activated carbon recovery processes to the treatment of low-grade or "slimy" gold ores has indicated that notable savings in plant investment and operating cost can be made as compared with conventional practice. Bureau of Mines metallurgists at the Salt Lake City Metallurgy Research Center continued work during the year to develop improved gold recovery techniques. Tests at a carbon-in-pulp pilot plant operated in cooperation with the Homestake Mining Co. at Lead, S.Dak., showed that 90% to 95% of the gold in a 0.15-ounce-per-ton slime feed could be cyanide leached and recovered on granular activated carbon. Based on the tests, construction of a full scale plant was started, and the company expected to complete by February 1973, a 2,350-ton-per-day carbon-in-pulp unit which will replace a more costly plate-and-frame filter-type slime-treatment plant. Continued development of a Bureau-invented pressure stripping process for recovering gold from loaded carbon showed that savings could be achieved in stripping time, labor, and reagents. Carbon-column gold extraction methods developed by the Bureau were utilized at the Carlin and Cortez gold operations in Nevada to treat wash solutions before discharge to tailings ponds. Operating data on 4-foot-diameter expanded-bed carbon columns with solutions assaying 0.008 ounce of gold per ton showed recoveries up to 75%, and further testing was in progress to improve on this yield.

[14] U.S. Bureau of Mines. Gold: Philippines. Mineral Trade Notes, v. 69, No. 5, May 1972, pp. 11–13.

Pilot plant studies were conducted at the Bureau of Mines Reno Metallurgy Research Center to improve gold recovery from carbonaceous gold ores using oxidation procedures based on use of chlorine and sodium hypochlorite.[15] Treatment with 20-pounds-per-ton sodium hypochlorite solution at 50° C for 4 hours followed by cyanidation resulted in 90% gold extraction. A chlorine pretreatment produced about the same results in longer time but at lower temperature. Electrolyzing a pulp prepared with a brine solution proved equally effective, with power consumption on the order of 60 kwhr per ton of ore. A patent was issued on the process developed from the work.[16] Also patented were gold extraction processes using malononitrile in place of cyanide for solution followed by collection on an anion-exchange resin[17] and using isopropyl alcohol to recover gold from a chlorinated brine solution followed by precipitation of gold with aqueous sulfur dioxide.[18] Phosphorus took part in a unique method devised to extract gold and other metals from dilute aqueous solutions.[19]

Seismic and other geophysical measurements revealed levels of stratification and boundaries of Tertiary channels containing gold in the Badger Hill area of Nevada County, Calif.[20] It was demonstrated that 30 percent of the drilling expenditures for exploring the deposits could have been saved by using geophysical methods initially. Geochemical surveys showed gold and silver anomalies in three areas of the Brooks Range, Alaska, to accompany base-metal anomalies.[21] One of the areas of interest was an unexplored zone in carbonate rocks north of the Wiseman and Chandalar districts. Placer gold and tin deposits were described in a text accompanying a map of the Teller area of the Seward Peninsula, Alaska.[22] Reworked glacial deposits from Alaska's Seward Peninsula were cited as the source of offshore gold in the northern Bering Sea.[23] Values in one area near Nome were reported as high as 920 ppb ($1.48 per cubic yard at $50 per ounce). Beach deposits on the east shore of Bristol Bay, Alaska, were examined for gold. Although auriferous deposits were occasionally as large as 1 acre in areal extent, they were seldom more than 6 inches thick.

The maximum gold content found was 0.007 ounce per ton.[24]

The distribution of gold in altered bedrock was studied in the Empire Mining district of Colorado, and high positive correlations found with tellurium, tin, bismuth, and silver.[25] Conversely, a negative correlation was found with manganese in the altered material. Based on the study, it was concluded that tellurium was the best "pathfinder" element to use in any widespread reconnaissance exploration for gold. Neutron-activation analyses of a wide variety of igneous rocks and minerals showed that gold in suites of unaltered igneous rocks associated with gold deposits was present in essentially the same amount as in compositionally equivalent rocks from unmineralized regions.[26] Gold content generally was highest in mafic rocks, decreasing in silicic rocks. Gold above background amounts was invariably found only locally in altered rocks, supporting other evidence that concentrations were either the result of remobilization or of secondary introduction. Interestingly, unaltered rhyolitic rocks ranging widely in age, provenance, and petrochemistry were uniformly low in gold (0.1-1 ppb), whereas calc-alkaline rocks from western U.S. batholiths were relatively high (0.5–10 ppb).

Descriptions and references to information on placer gold deposits were published for Arizona [27] and New Mexico.[28] Techniques of scuba diving for placer gold were described in a California publication.[29] Maps were published showing the distribution of gold and silver in several areas of Sierra County, N. Mex.[30] and of gold and copper in the Golconda and Iron Point Quadrangles, Nevada.[31]

A new process was developed for solution mining of gold and silver by introducing into permeable zones containing these metals solutions of chloride brines, with "residual oxidation potentials" over 500 millivolts, recovering the solution, and precipitating the precious metals with hydrogen sulfide.[32] In Yakutsk, U.S.S.R., the Scientific Research Institute for Rare Metals (Irkutsk) conducted field experiments to prevent refreezing of soil, which delays gold mining operations during part of the year.[33] A foam mixture was spread over the soil surface in several layers and mixed with snow to form a porous cover 1.5 meters thick. At the Vaal Reefs gold mine near Klerksdorp, the Republic of South Africa, gold ore, finely ground, was pumped to the surface from a depth of 7,200 feet using a new hydraulic hoisting system. Pumping capacity was equivalent to 25,000 dry tons of ore per month.

The Chamber of Mines of South Africa continued to publish its quarterly series entitled, Gold Bulletin, containing articles on new uses for gold and abstracts on new technology.[34] The January issue reviewed the optical and heat reflecting properties of very thin gold films; the Republic of South Africa research in gold mining and metallurgy was described in the July issue.

Bureau of Mines researchers developed a process including incineration, caustic leaching, smelting, and electrolysis to economically recover precious metals and copper from low-grade, complex electronic scrape.[35] In processing sweated aluminum electronic scrap, researchers developed and

Year total	1,495,108	1,449,943

tested molten-salt electrorefining processes.[36] High quality aluminum was recovered at 94% recovery rates and a copper-gold-silver anode product was treated, achieving recovery rates of 98% of the contained metals.

To develop a better understanding of cyanide reactions in electrodeposition, Bell Telephone Laboratories studied behaviors in various baths using cyclic voltrammentry and galvanostatic transients.[37]

Gold/copper characteristics were the subjects of several investigations, including diffusion of copper through thin gold electroplates,[38] annealing and cold-working properties of Cu_3Au,[39] and the advantages of gold electrodeposited at very low current onto a coarse-grained copper surface for use as a substrate for Permalloy films.[40]

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Unless otherwise indicated, production is on the basis of mine output.

[2] Gold is also produced in Bulgaria, Czechoslovakia, Spain, and small quantities probably in Argentina, Burma, East Germany, Hungary, Thailand, and several other countries. Data for these countries are not available. Data are also lacking on clandestine activities.

[3] Bullion only; excludes gold from placer operations for which no data are available.

[4] Purchased by Bank of Monrovia.

[5] Contained in blister copper, refinery muds, and electrolytic copper.

[6] Refinery production for Japan was as follows: 1970—709,338 ounces; 1971—772,652 ounces; 1972—845,628 ounces.

[7] New Guinea only.

Graphite

By David G. Willard[1]

Natural graphite remained in tight supply in 1972. Domestic consumption rose, largely as a result of the recovery in the metals industry, while domestic production declined further and production in certain key foreign countries fell. Since imports rose by a lesser amount than estimated consumption, and exports were also higher, a probable drawdown of supplier and consumer stocks was indicated, despite an increase in releases from the national stockpiles. Prices of imported supplies were up sharply, particularly for crystalline graphites, on account of both tightness in the market and devaluation of the dollar. Domestic prices temporarily held the line, but they also rose in early 1973.

The manufactured graphite industry enjoyed a booming year, especially in the second half, again due to the revitalized metals industry market. Demand for electrodes, the industry's staple product which accounts for the bulk of manufactured graphite tonnage, registered a strong increase. Sales of most other manufactured graphite products also exhibited a healthy upswing.

Legislation ana Government Programs.—Tight supply markets kept up consumers' interest in disposal of surplus graphite from the national stockpiles. As a result, virtually all surplus graphite in the stockpiles was committed to purchasers in competitive

offerings, although actual shipments were scheduled over periods as long as 5 years. Inventories shown in table 2 omit all committed surplus stocks. Comparison with the December 31, 1971 inventory indicates a disposal of 10,363 tons during 1972; however, actual shipments totaled only about 3,000 tons, 45% greater than the 2,100 tons entering the market in 1971.

An administration proposal to reduce the objectives of many stockpiled materials, including graphite, and dispose of the resulting surpluses was under consideration in early 1973.

DOMESTIC PRODUCTION

Production of natural graphite in the United States declined further in 1972, although at a slower rate than the year before. The only operating mine continued to be that of Southwestern Graphite Co. near Burnet, Tex., which produced a small flake crystalline graphite.

Interest in domestic graphite mining was stimulated by the growing shortage and higher prices of imported natural graphite. Several former graphite mines and other properties were being considered for investigation during the year. A deposit in Alaska, estimated to be quite large, was investigated by the Geological Survey. Minor production has occurred there in the past, but its remote location and lack of access as yet render it uneconomic at current prices.

Production of manufactured graphite regained an upward trend in 1972 after slipping slightly the year before. Ouput of 275,311 tons was up 7% from the 256,137 tons produced in 1971. Total value of production increased 17% to $183.6 million from $157.3 million the previous year.

All metallurgical uses of manufactured graphite showed marked improvement as the metals industries recovered from their slump of 1970–71. Most other uses, such as mechanical products made of graphite, also fared well. The outlook for graphite fibers brightened somewhat as the result of its initial commercial acceptance in specialty sporting goods, which represents its first nondefense application.

Manufactured graphite was produced in 26 plants owned by 18 companies during 1972. Some production may have taken place at other locations as well, particularly by users for in-house consumption. The considerably augmented list, as compared to that published last year, includes a number of plants making specialty products such as high-modulus fiber which had not been included in the manufactured graphite survey in previous years. The companies and plant locations were as follows:

Company	*Plant Location*
Airco, Inc., Speer Div	Niagara Falls, N.Y. Punxsutawney, Pa. St. Marys, Pa.
Avco Corp., Avco Systems Div	Lowell, Mass.
The Carborundum Co., Graphite Products Div	Hickman, Ky. Sanborn, N.Y.

Ultra Carbon Corp	Bay City, Mich.
Union Carbide Corp	Niagara Falls, N.Y. Yabucoa, P.R. Columbia, Tenn.
Wickes Engineered Materials	Saginaw, Mich.

CONSUMPTION AND USES

A strong upsurge in consumption of natural graphite in 1972 reflected the increased output of the metal industry. Demand in most refractory uses and other mill and smelter applications was significantly higher than in the two previous years. Consumption was up only a little in other uses of natural graphite.

Table 3 excludes the consumption by numerous small consumers. It is estimated that consumption in 1972, including small consumers, totaled 70,000 tons, a gain of 15% to 20% above the 1971 total. Most of the increase is estimated to have been in refractories and steel mill uses.

Table 3.—Consumption [1] of natural graphite in the United States in 1972, by use

(Short tons)

Use	Crystalline		Amorphous [2]		Total	
	Quantity	Value	Quantity	Value	Quantity	Value

Total	18,381	4,716,831	29,393	5,118,773	47,774	9,835,604

[1] Consumption data incomplete. Excludes small consuming firms.
[2] Includes mixtures of natural and manufactured graphite.
[3] Includes ammunition and packings.
[4] Includes antiknock and other compounds, drilling mud, electrical and electronic products, insulation magnetic tape, small packages, and miscellaneous and proprietary uses.

PRICES

Domestic price quotations for natural graphite continued unchanged in 1972, the second successive year of price stability. Price guidelines under Phase II and the availability of substitute materials together held prices in line. Such stability could not be maintained in the face of higher prices for imports and other cost increases, however, and the prices of most graphite rose in early 1973.

Domestic prices, as quoted by the Chemical Marketing Reporter (formerly Oil, Paint, and Drug Reporter), January 1, 1973, on an exwarehouse basis, were as follows:

	Per pound
No. 1 flake graphite, 90% to 95% carbon	$0.32–$0.42
No. 2 flake graphite, 90% to 95% carbon	.239– .32
Powdered crystalline graphite:	
88% to 90% carbon	.184– .27
90% to 92% carbon	.255– .275
95% to 96% carbon	.29– .399
Powdered amorphous graphite	.0626–.195
Powdered amorphous or crystalline graphite, minimum of 97% carbon	.28– .36

Prices of imported crystalline graphite rose during the year, as is shown by the comparison below of yearend prices, f.o.b. sources, quoted in the Engineering and Mining Journal (after conversion from metric tons). Factors causing import prices to go up included higher world demand, smaller production in Sri Lanka (formerly Ceylon), and devaluation of the dollar. Amorphous graphite prices showed no change from the year before.

	Per short ton	
	1971	1972
Flake and crystalline graphite, bags:		
Sri Lanka	$133–$241	$152–$259
Germany, West	143–855	163–929
Malagasy Republic	86–281	122–336
Norway	83–132	91–145
Amorphous, nonflake, cryptocrystalline graphite (80% to 85% carbon):		
Mexico (bulk)	22	22
Korea, Republic of (bags)	22	22

These quotations represent a total range of prices. Actual prices are negotiated between buyer and seller for each individual shipment. A better guide to price trends is the average value per ton, which can be determined from table 5, although it should be kept in mind that these prices are largely for shipments of unprocessed graphite. The average values for the major types of imported graphite in 1972 were as follows:

Crystalline flake, lump, chip, or dust	$160 per ton
Other natural, crude and refined	$ 47 per ton

FOREIGN TRADE

Exports of natural graphite rose sharply in 1972, in contrast to the previous year's small decline. The total of 7,289 tons was 27% greater than the 5,733 tons sold abroad in 1971 and exceeded the shipments in all previous years on record except 1969. Canada remained the best customer, taking 3,523 tons, almost double the amount of the previous year. Sizable increases also occurred in exports to Japan and West Germany.

Imports for consumption were also higher

[1] Not elsewhere classified.

in 1972, amounting to 64,135 tons which was 11% above the 57,756 tons imported in 1971. The total was the third highest on record, surpassing all years except 1968 and 1970. Crystalline flake graphite imports rose 44% to 7,043 tons, the largest amount since 1956. Imports of other types of graphite increased from 52,874 tons in 1971 to 57,092 tons in 1972, a gain of 8%. Increased demand plus the drop in 1971 imports combined to boost the requirement for foreign supplies to these near record heights.

WORLD REVIEW

World production of graphite decreased in 1972. The downswing, coupled with a probable rise in world demand, further aggravated the supply problem. Supplies of premium grades remained especially tight. A decline in exports by Sri Lanka (formerly Ceylon), stemming from the adjustment problems of their newly nationalized industry, was a primary cause of the supply shortage, and an increase in the demand for high-purity graphite in electronic and other specialized uses added to the imbalance. The large decline in output of low-grade material in the Republic of Korea was less serious in nature. Rising production of metals increased the demand for other grades, but supplies were adequate to meet the needs.

Brazil.—Graphite deposits were discovered near Niteroi in the vicinity of Rio de Janeiro.[2]

Malagasy Republic.—Riots brought about the fall of the Tsiranana Government in May, and it was replaced by a military administration under General Ramanantsoa. Amid conflicting political pressures the new government has maintained the existing private enterprise system but has not clearly indicated its future economic policies. The resulting uncertainty created apprehension about the future supply of Malagasy graphite, but at yearend appeared to have had little adverse effect on production.[3]

Riots closed the port of Tamatave, outlet for all of the country's graphite exports, during part of the month of December. Potential further disturbances caused ocean shipping companies to avoid Tamatave for a period thereafter, following which ships would dock at the port only on payment of a 20% surcharge. As a result, graphite shipments were greatly delayed.[4]

Sri Lanka (formerly Ceylon).—Adjustment problems resulting from takeover of the graphite mines by the State Graphite Corporation caused production to drop in 1972. However, a renewed interest in prospecting was shown by the increased activity of the Geological Survey. Geophysical investigations and drilling were carried out near Bogala, the country's largest graphite mine, and at two other locations in the southwestern part of the island.[5]

The export duty on graphite, which had been raised to 50% in 1970, was reduced back to 25% in January 1972. However, no comparable reduction in prices occurred.[6]

Yugoslavia.—A deposit estimated to contain 11 million short tons of high-grade graphite ore was discovered near Razanj in Serbia. Plans were announced to begin exploiting the deposit in 1973.[7]

Other Countries.—Studies of known graphite deposits with a view to future development or expansion were announced in India, Italy, and Mozambique.[8]

TECHNOLOGY

As in previous years, technological developments during 1972 centered on uses of manufactured graphite, particularly composite materials containing graphite fibers. But some advances affecting the use of natural graphite also occurred.

A study carried out in India demonstrated that column flotation can result in a higher percent recovery than conventional flotation methods because it reduces entrapment of gangue in the mineral during agitation.[9]

Research into the possibility of a reaction affecting graphite in contact with aluminum metal indicated that an oxide layer on the aluminum normally prevents the metal from wetting graphite, but the presence of cryolite can provide a flux which permits a reaction to occur.[10]

Significant growth is anticipated for the powdered metals industry. Graphite is the source of carbon in many powdered metal mixes. One important gain was the announcement that future rotary engines in General Motors cars will have powdered metal rotors.[11]

The majority of manufactured graphite research continued to be applied to the development of composite materials using graphite fiber. Efforts to combine the fibers with metal matrixes, which would be stronger than graphite/plastics composites, concentrated on alumina and aluminum. Initial research on one such composite was carried out by the National Aeronautics and Space Administration (NASA) at the Marshall Space Flight Center.[12] Other programs have been directed toward combining the high-cost graphite fibers with lower cost glass fibers in order to produce a composite material at a lower overall cost.[13]

In another area of use, development of a nickel-coated graphite anode for the electrolysis of chloride salts eliminated contamination of the product which previously resulted from disintegration of uncoated anodes.[14]

Patents incorporating graphite covered a wide spectrum of uses in 1972. Two included graphite in lubricating compounds and one patent each made use of it in coatings, cleaning compounds, pigments, packings, and washers. A screening mechanism was developed for use with either graphite or mica.

Gypsum

By Avery H. Reed [1]

The gypsum industry operated at record levels in 1972. Output of crude and calcined gypsum set new annual records. Imports of crude gypsum were an alltime high. Sales of gypsum products were higher than for any other year.

Republic Gypsum Co. reopened the Rosario mine and plant in Santa Fe County, N. Mex., and Temple Gypsum Co. completed its new processing plant at West Memphis, Ark.

The gypsum resources of Oklahoma were described.[2]

Many companies were concerned about environmental problems at gypsum plants. Rigid air pollution standards could force extensive plant revisions. The disposal and possible use problems of waste gypsum at fertilizer plants were examined.

[1] Each mine, calcining plant, or combination mine and plant is counted as 1 establishment.
[2] Excludes byproduct gypsum.

DOMESTIC PRODUCTION

Thirty-six companies mined crude gypsum at 65 mines in 21 States. Of these mines, 12 were underground and 53 were open pit. Output increased 18% to 12,328,000 tons, 13% above the 1959 record. Leading States were Michigan, Texas, California, Iowa, and Oklahoma. These five States, with 30 mines, accounted for 59% of the total crude gypsum. Leading companies were United States Gypsum Co. (13 mines), National Gypsum Co. (7 mines), Georgia-Pacific Corp. (7 mines), The Flintkote Co. (2 mines), and The Celotex Co. (3 mines). These five companies, operating 32 mines, produced 75% of the total crude gypsum. Leading mines were U.S. Gypsum's Plaster City, Calif., mine, and Alabaster, Mich., mine; National's Tawas City, Mich., mine, and Shoals, Ind., underground mine; and U.S. Gypsum's Southard, Okla. mine.

Fourteen companies calcined gypsum at

NA Not available.

76 plants in 30 States. Output increased 26% to 12,005,000 tons and set a new annual record. Leading States were Texas, California, New York, Iowa, and Georgia. These five States, with 29 plants, accounted for 43% of the total calcined gypsum. Leading companies were United States Gypsum Co. (23 plants), National Gypsum Co. (19 plants), Georgia-Pacific Corp. (10 plants), The Flintkote Co. (5 plants), and Kaiser Gypsum Co. Inc. (5 plants). These five companies operated 62 plants, and produced 85% of the total calcined gypsum.

Valley Nitrogen Producers Inc., Occidental Petroleum Corp., and Collier Carbon & Chemical Corp. sold 278,600 tons of byproduct gypsum for agricultural use in California.

The United States is the world's leading producer of gypsum, accounting for 19% of the total output.

CONSUMPTION AND USES

Apparent consumption of gypsum, as measured by production plus imports minus exports, was 20.0 million tons, an increase of 21% and a new annual record. Imports were 39% of the total.

Of the total gypsum supply, 5.2 million

tons, or 26%, was sold or used uncalcined. Of the total uncalcined gypsum, 3.9 million tons, or 76%, was sold or used in portland cement, and 1.1 million tons, or 22%, was used in agriculture. In addition, 279,000 tons of byproduct gypsum was sold for agricultural uses.

The leading consuming sales regions for gypsum in portland cement were the Middle Atlantic and the West South Central, which accounted for 51% of the total. For agricultural gypsum, the Pacific sales region accounted for 96% of the total. It has been estimated that the alkali soils of the Western States could benefit by as much as 12 tons of gypsum per acre.

Of the total calcined gypsum, 92% was used for prefabricated products and 8% was used for plasters. Of the prefabricated products, 76% was regular wallboard, 15% was type-X wallboard, and 3% was lath.

The leading consuming sales regions for prefabricated products were the South Atlantic and the East North Central, which together accounted for 35% of the total. For plaster, the East North Central and the South Atlantic accounted for 45% of the total.

PRICES

The value of crude gypsum increased from $3.75 per ton in 1971 to $3.93. The value of calcined gypsum increased from $15.96 in 1971 to $16.32 per ton. The average value of byproduct gypsum sold was $5.11 per ton.

The average value of gypsum products increased from $25.73 in 1971 to $28.88 per ton. Prefabricated products were valued at $38.06, plasters at $31.53, and uncalcined products at $5.18 per ton.

Quoted prices for gypsum are published monthly in the Engineering News-Record. Prices quoted December 21, 1972, showed a wide range, based on delivered prices. Regular ½-inch wallboard prices ranged from $42 per thousand square feet at Dallas to $85 at Chicago. Prices for plaster ranged from $31 per ton at Dallas to $58 per ton at Minneapolis.

[2] Includes a small quantity of other unspecified lath.
[3] Data may not add to totals shown because of independent rounding.
[4] Includes a small quantity of 5/16-inch, ⅝-inch firetardboard, and ¾-inch gypsumboard.

FOREIGN TRADE

Imports of crude gypsum were 7.7 million tons, of which 77% came from Canada, 16% from Mexico, and 6% from Jamaica. Exports of crude gypsum totaled 51,000 tons.

Although there are vast deposits of gypsum in the United States, there are no known deposits along the coastlines. There are large tidewater deposits in Canada and Mexico from which shipments may be made to coastal cities at a lower delivered price than domestic gypsum.

WORLD REVIEW

Canada.—Canada was the second leading producer of crude gypsum. Output in 1972 was 7.9 million tons of which 5.9 million tons was exported to the United States.

U.S. Gypsum Co., National Gypsum Co., Georgia-Pacific Corp., B. S. Parsons, and D. McDonald mined gypsum in Nova Scotia. U.S. Gypsum Co. and Canada Cement Lafarge Ltd. mined gypsum in New Brunswick. The Flintkote Co. mined gypsum in Newfoundland.

In the western provinces, Domtar Construction Materials Ltd. and Westroc Industries Ltd. mined gypsum in Manitoba. Westroc Industries Ltd. also mined gypsum in British Columbia.

Westroc Industries Ltd. announced plans to construct a $7.2 million gypsum wallboard plant near Montreal.

France.—France was the third leading gypsum producer, with shipments of over 6 million tons. Most of the gypsum was exported.

India.—Deposits of gypsum covering 700 square miles and estimated at 469 million tons have been discovered in the Kohat area. Gypsum reserves in Jammu and Kashmir are estimated at 79 million tons.

Netherlands.—Plans were announced for a new plant at Born for making plasterboard from byproduct gypsum. Annual capacity is estimated at 400,000 tons of gypsum.

South Africa, Republic of.—A new plant went on stream at Palabora, treating the byproduct gypsum from the phosphoric acid plant. Products of the new plant are sulfuric acid and a clinker that can be ground for portland cement.

Spain.—Spain was the sixth leading gypsum producer, with shipments of nearly 5 million tons. Most of the material was exported.

U.S.S.R.—The U.S.S.R. ranked fourth in gypsum production, with shipments of more than 5 million tons. Most of the gypsum was consumed in the Soviet Union.

TECHNOLOGY

Interest continued in the use of byproduct gypsum for producing wallboard and plaster. Sabina Industries holds the United States and Canadian rights to the patented Giulini process for the recovery of high-quality gypsum from waste gypsum. There are very large quantities of waste gypsum that must be used or disposed of.

American Cyanamid Co. announced that a new gypsum board plant would be built at Savannah, Ga. The gypsum would be recovered by a Japanese process from the waste water of the company's titanium dioxide plant.

Helium

By Gordon W. Koelling [1]

Sales of high purity helium (99.995% purity) in the United States during 1972 increased 9% to a total of 489 million cubic feet.[2] Approximately 36% of this total was sold by the Bureau of Mines and 64% was accounted for by private industry plant sales. Exports of high purity helium, all by private industry, totaled 138 million cubic feet in 1972. The f.o.b. Bureau of Mines plant price for high purity helium sold during the year remained at $35 per thousand cubic feet while private industry plant prices averaged $21 per thousand cubic feet.

In compliance with an order of the U.S. District Court for the District of Kansas issued on March 27, 1971, the Bureau of Mines continued to accept helium during 1972 under three of four conservation contracts whose termination provisions had been invoked by the Secretary of the Interior. This order was affirmed on appeal on the ground that the requirements of the National Environmental Policy Act had not been complied with. On November 13, 1972, the Department released an environmental impact statement prepared in furtherance of an evaluation of the environmental consequences of termination of the contracts.

A ruling made by the U.S. Court of Claims on January 21, 1972, held that the Government had materially breached its agreement with the fourth contractor. The issue of damages is pending. This firm continued to deliver helium to the Bureau of Mines for storage to its account, pursuant to an interim storage agreement until expiration of the agreement on September 28, 1972.

DOMESTIC PRODUCTION

A total of 12 helium extraction plants were in operation during 1972. Of these two were owned by the Federal Government and operated by the Bureau of Mines, five were private industry plants extracting helium primarily for long-term conservation storage, and five were private industry plants producing helium for independent sale to commercial (non-Federal) customers.

Total helium extracted from natural gas during 1972 declined approximately 10% to 4,089,501 thousand cubic feet despite a 9% increase in the output of high purity helium to 627,250 thousand cubic feet. Approximately 85% of total helium extracted was crude helium[3] and 15% was high purity helium produced for sale. About 92% of crude helium production was from private industry conservation plants and 72% of high purity output was from private industry plants producing for sale to commercial customers. The remaining 8% of crude and 28% of high purity helium produced was extracted by Bureau of Mines plants.

Of the 438,665 thousand cubic feet of helium produced by the Bureau of Mines Keyes and Exell plants in 1972, approximately 88% was extracted from natural gas supplied by a private natural gas pipeline company on a gas-processing contract basis. The remaining 12% was extracted from natural gas that was produced from the Bureau of Mines Cliffside gasfield primarily in order to create additional reservoir space for helium conservation storage. All helium extraction from Cliffside natural gas occurred at the Exell plant.

Net deliveries to helium conservation system[4]	506,733	263,057
Inventory at end of period[1]	11,474	16,142
Total disposal	691,833	452,774

[1] At Exell and Keyes plants and at Amarillo shipping terminal.
[2] Excludes conservation helium produced from native gas withdrawal wells at Cliffside field, which have been invaded by stored helium.
[3] Includes only those quantities produced for sale; quantities entering conservation after purification are included under crude helium.
[4] Excludes return of conservation helium produced as indicated in footnote 2 to conservation storage system.

Extensive modernization of the Exell plant was incomplete at yearend because of delays caused by technical problems. The new facilities included in this modernization program are for the purpose of consolidating operations, improving efficiency, and facilitating underground helium storage operations.

CONSUMPTION AND USES

Domestic sales of high purity helium rose 9% during 1972 in a moderate reversal of a 5-year declining trend. Much of the 1972 increase was attributable to the overall improvement in the Nation's economy and increased requirements for helium in research and in breathing mixtures.

Although the quantity of helium sold by the Bureau of Mines in 1972 was almost the same as in 1971, the share of the domestic helium market accounted for by the Bureau declined from 39% in 1971 to 36% in 1972. This resulted from a lack of growth in the need for helium on the part of Federal agencies, which are required by law to purchase all of their major requirements from the Department of the Interior. The f.o.b. Bureau of Mines plant price, which is set at $35 per thousand cubic feet for the purpose of financing the long-range helium conservation program, was not competitive with the 1972 average f.o.b. private plant price of $21 per thousand cubic feet.

Approximately 30% of Bureau sales in 1972 were through purchases by Federal agencies from private distributors under General Services Administration contracts which required the distributors to purchase equivalent quantities from the Bureau of Mines. These contracts made relatively small quantities of helium readily available to Federal installations and reduced freight charges for small purchases.

Domestic consumption of helium during 1972 was primarily for purging and pressurizing rockets and spacecraft, research, welding, maintenance of controlled atmospheres, leak detection, and cryogenics. Demand occurred principally in the States along the west and gulf coasts.

All helium sold by the Bureau of Mines was shipped in gaseous form in cylinders, highway semitrailers, or railway tank cars. Private industry plants shipped helium in both gaseous and liquid form. Much of the helium transported in liquid form was delivered by semitrailers to distribution centers, where most of the product was gasified and compressed into small cylinders and trailers for delivery to consumers.

National Weather Service	3,066	2,940
Other [1]	1,062	3,346
Total Federal agencies	138,563	121,135
Non-Federal customers [2]	35,063	52,440
Grand total	173,626	173,575

[1] Includes quantities used by Bureau of Mines.

[2] Most of this was purchased in bulk by commercial firms, repackaged in smaller containers, and then sold to Federal installations under contract arrangements with the General Services Administration.

CONSERVATION

The purchase of crude helium by the Bureau of Mines, under the terms of contracts entered into with three private producers in 1961, continued in compliance with a court order obtained during 1971 by Cities Service Helex, Inc., National Helium Corp., and Phillips Petroleum Co. The Bureau also accepted helium from the contractor not involved in that litigation, Northern Helex Co., for storage to that company's account until expiration of an interim storage agreement on September 28, 1972.

Helium held in the Bureau of Mines conservation storage system, which includes the conservation pipeline system and the partially depleted Cliffside gasfield near Amarillo, Tex., increased 11% during 1972 to a yearend total of 35,630,904,000 cubic feet. Of this total, 97% was stored under the Bureau's conservation program and the remaining 3% was stored under contract for private producer's own accounts. Approximately 8% of the net addition to the helium conservation system in 1972 was accounted for by deliveries from Bureau plants, 76% was acquired from private industry conservation plants for the conservation program, and 16% was added to storage under contract for private producers' own accounts. Most of the latter was accounted for by quantities stored under an interim agreement for the account of Northern Helex Co.

Table 6.—Summary of Bureau of Mines helium conservation system [1] operations, 1971 and 1972

[1] Includes some helium stored for the account of Cities Service Cryogenics, Inc., which pipes its output to Cities Service Helex, Inc., for purification.

RESOURCES

Proved and probable helium reserves (in natural gas with a minimum helium content of 0.3%) in the United States, exclusive of those quantities in conservation storage at the Cliffside field, were estimated at 120.2 and 15.7 billion cubic feet, respectively, as of December 31, 1972. The total 135.9 billion cubic feet of proved and probable reserves available at yearend was almost 6% less than at the beginning of the year.

Although proved and probable helium reserves were contained in the natural gas reservoirs of over 100 gasfields located in 10 States, the bulk of reserves were in four fields: the Greenwood field in Kansas and Colorado; the Hugoton field in Kansas, Oklahoma, and Texas; the Keyes field in Oklahoma; and the West Panhandle field in Texas. Almost 83% of proved and probable reserves were in fields being produced at yearend 1972. Approximately 51% of the helium-rich (0.3% helium content) natural gas produced was being processed for helium extraction, and helium contained in the remaining helium rich natural gas output was being wasted incident to the consumption of the gas.

The Bureau of Mines continued its efforts to identify helium resources in the United States and other parts of the world. A total of 369 natural gas samples from 25 States and four foreign countries, Australia, Canada, Indonesia, and the United Kingdom, were collected and analyzed for helium content during 1972. None of these samples indicated the occurrence of significant helium resources.

FOREIGN TRADE

Exports of high purity helium in 1972 increased 6% and comprised 22% of the U.S. helium industry's total high purity sales as compared with 23% during 1971. All exports were from private industry extraction plants, which depended on foreign markets for 30% of their total high purity sales in 1972. Most of the quantity shipped was destined for Western Europe.

WORLD REVIEW

Helium produced outside the United States during 1972 totaled an estimated 122 million cubic feet. Canada produced approximately 35 million cubic feet from a single plant in Saskatchewan, mostly for export to Japan and other Asian countries, although some was used in Canada. A plant in France produced about 7 million cubic feet of helium as a byproduct of nitrogen removal operations. The countries of Eastern Europe extracted an estimated 80 million cubic feet during the year.

During 1972, Petrocarbon Developments, Ltd., of the United Kingdom was in the process of planning the construction of a helium and nitrogen extraction plant which it is to build under contract in Poland. This plant is to separate helium and nitrogen from natural gas that has a nitrogen content of about 45%. A helium purification and liquefaction unit to be integrated with the nitrogen removal process is to have a high purity helium output capacity of 150 million cubic feet per year. Completion of this project was scheduled for mid-1974.

TECHNOLOGY

Gulf General Atomic Co., a subsidiary of Gulf Oil Corp., initiated a preliminary planning study of a helium gas turbine for the Atomic Energy Commission during 1972. This study is to assess the commercial feasibility of developing a helium-cooled nuclear reactor and employing the same helium in a closed cycle to drive the gas-turbine generator. This would eliminate the steam-turbine cycle ordinarily used in powerplants and allow heat rejection to take place directly to air in dry cooling towers. It would also eliminate thermal pollution of streams, and would allow utility companies more flexibility in picking their powerplant sites. The gas turbines themselves could be located inside the same containment vessel that housed the reactor core, thus offering a capital cost savings.

Two Japanese companies, Teijin Ltd., and Nippon Sanso KK, reportly have developed a helium recovery and refining system that utilizes selective permeability of helium gas through synthetic high polymer film. Operating costs for such a system are stated to be approximately 30% lower than for conventional methods, although the initial investment for equipment is similar. The new system is expected to find wide application in the recovery and refining of helium from gas mixtures used for breathing in deep-sea operations, or from contaminated helium evaporated from hyper-refrigerating equipment.

Iron Ore

By F. L. Klinger[1]

The relatively low demand for iron ore that developed during 1971 carried over into the first half of 1972. With large inventories of ore at mines and consuming plants, mine production or shipments were reduced in many of the principal iron ore producing and exporting countries. There was a strong increase in demand in the latter part of the year, but the consequent rise in production and shipments was not quite enough to push world production or trade above the levels of 1971. Consumption of iron ore, however, increased about 9% in the United States, 6% in the European Economic Community (EEC), and also increased in Japan and the Soviet Union in 1972.

Production and exports of iron ore declined substantially in the United States, Canada, Chile, Venezuela, and Angola, while small to moderate increases in production or exports were reported from Australia, Brazil, India, Liberia, Mauritania, Peru, and the U.S.S.R., compared with those in 1971. Imports of iron ore by the United States and Japan declined by 3 to 4 million tons but increased slightly in the EEC and probably increased to some extent in East European countries which receive most of their ore supplies from the U.S.S.R. Canadian production and exports were hampered by strikes at some major mines and ports during the summer, while cutbacks in imports of ore by Japan in 1972 were further affected by a Japanese shipping strike which lasted from April to July.

Australia continued to be the world's leading exporter of iron ore in 1972, as well as the third largest producer after the U.S.S.R. and the United States. Japan, which imported more than 100 million tons of ore for the third consecutive year, remained the world's largest importer, followed by West Germany and the United States.

World shipments of iron ore pellets were estimated at 125 million tons in 1972, equivalent to about 95% of estimated world production capacity at the beginning of the year. The United States accounted for 43% of the total; Canada, for 18%; and 18 other countries for the remainder. World production capacity for pellets increased to an estimated 146 million tons annually by yearend, and 16 million tons of additional capacity was anticipated during 1973.

World output of prereduced iron ore appeared to be below the capacity of existing plants, partly due to technical problems. The Falconbridge Nickel Mines Ltd. plant at Sudbury, Ontario, was to close early in 1973, but a new plant was completed at Houston, Tex., in 1972 and another was scheduled for completion at Contrecoeur, Quebec in 1973.

Iron ore prices were relatively stable in 1972, but devaluation of the dollar and realignment of foreign currencies in 1971 were causing problems. Australian producers, whose contracts with Japanese importers were mainly based on dollar values prior to 1971, were pressing for upward adjustment of contractual prices. Swedish producers, whose contracts with European buyers are usually based on the krona, were forced late in 1972 to reduce export prices for 1973 deliveries by as much as 15% in order to meet competition in European markets from Australian and other foreign ores. However, U.S. prices for Lake Superior iron ores and pellets, delivered at lower lake ports, began to rise in December 1972, and by the beginning of the 1973 shipping season prices were 5% to 6% higher than those prevailing 1 year earlier.

In transportation of iron ore, the size of carriers continued to increase, with individual cargoes up to 166,000 tons reported in oceanborne trade and up to 55,000 tons on the Great Lakes. Some ocean cargoes of more than 200,000 tons were expected in

---

[1] Physical scientist, Division of Ferrous Metals—Mineral Supply.

1973. Capacity of offloading ports to receive large carriers was increased, especially in Japan and the United Kingdom. Ocean shipments of iron ore slurries increased to at least 1.3 million tons in 1972. Ocean freight rates were low in early 1972 but by yearend were approaching the high levels of early 1971.

EMPLOYMENT

The average number of men employed at U.S. iron ore mines and associated beneficiating plants was about 14,500 in 1972, a decline of 8.8% compared with the previous year. The reduction was mainly due to mine closures in Minnesota and New York, and to cutbacks in production in Minnesota and California.

The reduction in employment was accompanied by declines of 4.6% in output of crude ore and 6.2% in production of usable ore, compared with 1971. Total hours worked and the number of man-shifts were 9.6% less than in 1971 but productivity continued to rise. Output per man-shift increased 5.8% in crude ore and 3.9% in usable ore. Productivity in the Lake Superior district was 11% to 13% greater than the national average; this district accounted for 69% of total employment and 82% of U.S. production in 1972.

Employment and productivity data for 1972 are summarized in table 4. As in previous years, the employment figures do not include office workers at mines and associated beneficiating plants.

DOMESTIC PRODUCTION

Low demand for iron and steel, coupled with large stockpiles of ore at U.S. mines and consuming centers and a sharp reduction in export demand, led to the lowest production of usable ore from U.S. mines in 9 years. Output in 1972 was 6.6% less than in 1971 and 16% lower than in 1970. Mine shipments fared somewhat better, lagging behind 1971 levels for the first 8 months of the year, but with sharply increased demand and extension of the shipping season by several companies during the fourth quarter, 1972 shipments exceeded those of 1971 by 1% by yearend. Vessel shipments of ore from U.S. ports on the Great Lakes totaled 63.6 million long tons in 1972, 6% more than in 1971.

Despite the decline in total output of usable ore, production and shipments of iron ore pellets continued to increase. Pellets made up 71% of usable ore production and shipments in 1972 compared with 66% in 1971. The average iron content of usable ore produced also continued to rise, to 60.8%.

Crude ore production in 1972 was 4.5% less than in 1971. The average iron content of crude ore produced was 33.7%. The latter figure, however, represents total iron contained; the percentage of recoverable iron, as in the the taconite operations, is usually much less. The average content of recoverable iron in total crude ore produced was 24.4%. The ratio of crude ore produced per ton of usable product (excluding byproduct ore) in 1972 was 2.50:1, compared with 2.45:1 in the previous year. Production of direct-shipping ore was slightly more than in 1971, but the declining trend evident for the last 20 years was expected to continue.

The Lake Superior district produced 81.6% of the Nation's output of usable ore in 1972 and about 83% of all crude ore mined. Minnesota accounted for 65% of the total output of usable ore; Michigan for 15.5%, Wisconsin for 1% and the remainder was produced in 17 other States, of which the principal producers were California, Missouri, Wyoming, Utah, New York, and Pennsylvania. Production came from 58 mines, including 48 open pits, seven underground mines, and three combined underground and open pit operations. The number of operating mines was 16 fewer than in 1971, but this reduction was mainly due to temporary inactive status of a number of smaller producers which continued to ship ore from stockpiles in 1972.

In Minnesota, United States Steel Corp. completed expansion of the Minntac mine and plant in August 1972. The expansion doubled production capacity for pellets to 12 million tons per year. Improvements in productive capacity for pellets were also evident at plants in Eveleth and Nashwauk, so that nominal productive capacity for pellets at Minnesota taconite operations was probably about 41 million tons per year at the end of 1972. No decisions were announced concerning construction of the proposed 4-million-ton pellet plant at Hibbing. In other developments, the Hill-Trumbull mine did not produce ore in 1972 and the property was returned to the fee owners by Mesaba Cliffs Mining Co. Jones & Laughlin Steel Corp. leased the Delaware properties on the western Mesabi from United States Steel Corp.; these properties are adjacent to the Hill-Annex mine and concentrator operated by Jones & Laughlin at Calumet and are expected to increase the company's production from Minnesota mines in 1973. A work stoppage affecting 1,300 employees of the Hanna Mining Co. lasted from June 9 to July 22 and virtually ceased production at the Pierce natural-ore mine and at the Butler and National taconite plants during this period. Alleged pollution of Lake Superior, by taconite tailings discharged from the Reserve Mining Co. concentrator at Silver Bay, continued to be a controversial issue in 1972. The U.S. Department of Justice filed suit against the company in February and by midyear 17 other parties were permitted by the court to intervene. The States of Michigan and Wisconsin supported the Federal Government's case, while the company was supported by a number of county, municipal, and civil bodies.

In Michigan, Cleveland-Cliffs Iron Co. continued construction of the Tilden nonmagnetic taconite project near Ishpeming. Completion of the mine and concentrator, which will produce 4 million tons of iron ore pellets per year from 10 million tons of crude ore, is scheduled for mid-1974. Project design and construction is managed by Kaiser Engineers of Michigan, Inc., and the pelletizing plant will be supplied by Allis-Chalmers Corp. of Milwaukee, Wis. Cleveland-Cliffs also announced that production capacity for pellets at the Empire mine would be increased by 1.8 million tons annually by mid-1974. The expansion will cost an estimated $65 million and will raise production capacity for pellets to 5.2 million tons per year.

In California, the Beck mine in northern San Bernardino County had its first full year of production in 1972. The mine is operated by Standard Slag Co., producing lump and fine magnetite concentrates for export to Japan under a 5-year contract to supply 2.5 million tons of concentrate by the end of 1976. The company closed the Minnesota mine near Wabuska, Nev., in 1971 and shipped the last cargo of ore from Stockton, Calif., in March 1972. Ore from the Beck mine is exported from Los Angeles.

In Alabama, the Woodward Co. (division of the Mead Corp.) announced that its last operating blast furnace would be shutdown early in 1973. About 265 employees will reportedly be affected. The company had stopped mining ore late in 1970.

In New York, the Tonawanda Iron Division of American Standard Inc. shutdown its blast furnace at Tonawanda in June 1972. About 160 employees were affected. The company had been producing about 200,000 tons of pig iron per year, mainly from Mesabi hematite ores.

In Pennsylvania, the Cornwall underground mine of Bethlehem Steel Corp. was closed in June 1972 due to flooding of underground workings. The mine's power supply was cut off when heavy rains flooded the powerplant at Lebanon, Pa. After depletion of a small open pit ore body in 1973, the mine was expected to be permanently closed. The Cornwall mine is the oldest operating iron mine in the United States, and has produced ore continually since 1742.

In Texas, the country's third commercial plant for direct reduction of iron ore was completed at Houston by Armco Steel Corp. in 1972. Production capacity of the plant was reported to be 1,000 tons per day of metallized ore or pellets.

In Alaska, the economic feasibility of producing iron ore from low-grade titaniferous magnetite deposits near Klukwan was being studied by Henry J. Kaiser (Consulting) Co. of Oakland, Calif., for the Mitsubishi Corp. of Japan. The study was expected to be completed in 1972. Rights to mine the deposits are presently held by United States Steel Corp.

In Tennessee, the pelletizing plant of Cities Service Co. was reportedly completed in 1972. The plant will pelletize byproduct iron ore derived from processing of sulfides.

CONSUMPTION

Total consumption of iron ore and agglomerates in 1972 was 9.2% more than in 1971. Consumption during the first 7 months of 1972 was 7% less than in the corresponding period of 1971, but with the recovery of demand for iron and steel in the latter part of the year, consumption exceeded the 1971 level by the end of September and during the last 3 months of the year it was 38% greater than in the last quarter of 1971.

Consumption of iron ore and agglomerates in blast furnaces in 1972 increased by 9.8% compared with 1971, but consumption in steelmaking furnaces was 21% less. The continuing decline in consumption by steel furnaces was due mainly to the declining number of operating open-hearth furnaces. In blast furnaces, the weight ratio of iron ore and agglomerates consumed to hot metal produced in 1972 was 1.55:1 compared with 1.54:1 in the previous year.

The share of pellets in total consumption of iron ore and agglomerates rose to at least 52% in 1972, compared with 48% in 1971. Both domestic and foreign pellets are included in this figure. Domestically produced pellets made up 46% of total consumption, and 56% of the agglomerates consumed; corresponding figures for 1971 were 41% and 52% respectively.

Consumption data are shown in table 13 and 14. In these tables, iron ore concentrate used to produce pellets or other agglomerates at mine sites was not reported as iron ore consumed; its consumption was reported only when such agglomerate was shipped to the furnaces site and used (table 13). However, concentrate and fines used for production of agglomerates (mainly sinter) at blast furnaces and steel plants was reported as iron ore consumed (table 14), and consumption of agglomerates derived from this source is included in table 13. In table 14, the difference in weight between iron ore consumed and agglomerates produced is due mainly to additives such as lime, mill scale, flue dust, coke breeze, and other materials used in making agglomerates.

STOCKS

Stocks of iron ore at U.S. mines, docks, and consuming plants totaled 67.3 million tons on December 31, 1972. The total was nearly 15% less than one year earlier and was the lowest since yearend 1969. The unusually large inventories at the beginning of 1972, coupled with the relatively low level of demand for iron and steel which carried over into the first half of the year, tended to depress mine production as well as imports of iron ore during 1972. Total stocks of iron ore and agglomerates at yearend represented about a 6-month supply at the average monthly rate of domestic consumption in 1972.

PRICES

Published prices for Lake Superior iron ores and iron ore pellets, after increasing by 3% to 5% in 1971, were unchanged during the first 11 months of 1972. However, in February the bulk vessel freight rate for iron ore shipped from the head of the lakes to lower lake ports was increased by 12 cents per gross ton, to $2.37. The effect of this was to increase the price of some ore at lower lake ports, since any increase in transportation costs would be borne by the buyer.

In December 1972 several companies announced increases in base prices amounting to about 4.7% for natural ores and 3.9% for pellets. As of January 1, 1973, published prices for natural ores, basis 51.5% iron, rail of vessel at lower lake ports, were 54 cents per gross ton higher than a year earlier and the price of pellets was increased to 29.1 cents per long ton unit of contained iron. The new prices for natural ores, per gross ton, were as follows; Mesabi non-Bessemer, $11.71; Mesabi Bessemer, $11.86; Old Range non-Bessemer, $11.96; and Old Range Bessemer, $12.11. Any increase in transportation or handling costs was to be borne by the buyer.

The average value of usable iron ore shipped from domestic mines in 1972 (excluding byproduct ore) was $12.20 per long ton, f.o.b. mine, compared with $11.55 in 1971 and $10.80 in 1970. The values were calculated from producer's statements and approximated the commercial selling price less the cost of mine-to-market transportation. The increase in average f.o.b. value reflected higher market prices as well as the increasing proportion of pellets in domestic iron ore shipments. Pellets made up 71% of domestic shipments in 1972, compared with 66.4% in 1971, and 61.7% in 1970.

Although information on prices for foreign iron ores was very limited, indications were that prices during most of 1972 were unchanged or slightly lower than those of 1971. This appeared to be due to relatively low world demand for iron ore in the first 8 months of 1972 and was in contrast to rising price trends in 1970 and 1971. Prices for Brazilian and Swedish ores were stable while somewhat lower prices were indicated by exporters in Norway and Mauritania. Also, f.o.b. or c.f. prices for many foreign iron ores in 1972 appeared to be fixed under long-term contracts with Japanese buyers. The price situation was complicated, however, by devaluation of the dollar and realignment of foreign currencies in 1971, along with the fact that many iron ore delivery contracts were based on prices quoted in U.S. dollars. This resulted in loss of revenue for many exporters and was further complicated by rapidly rising ocean freight rates in the latter part of 1972. Consequently, there was increasing pressure for upward revision of dollar contract prices to compensate for the shifting exchange rates. At the same time, however, dollar-priced ores became cheaper in world markets, strengthening their competitive position relative to iron ores priced in other currencies. The latter situation, late in 1972, forced Swedish exporters, whose contracts are based on kronor prices, to reduce prices for 1973 deliveries by 12% to 15% for high-phosphorus ores and by 6% to 10% for other Swedish ores, in order to protect their traditional markets against competition from imports of iron ore from Australia and other countries.

Some published prices for foreign iron ores, believed to be applicable to deliveries in 1972 under contracts with Japanese buyers, are tabulated below. Because of widely differing chemical and physical properties and conditions of shipment, these prices are not necessarily comparable to prices for other foreign ores; they are presented here as possible indicators of price ranges for similar products in 1972.

Origin	Company or deposit	Type of product	Contract price	Terms and port
Angola	Cassinga	Lump, 64% Fe	$8.14/ldt	f.o.b. Porto Salazar.
	do	Fines, 64% Fe	6.50/ldt	Do.

TRANSPORTATION

The trend toward use of larger ore-carrying vessels to reduce unit transportation costs was continued in 1972 on the U.S. Great Lakes as well as in oceanborne trade.

On the Great Lakes, the vessel *Stewart J. Cort* of about 58,000-gross-ton cargo capacity was placed in service in May by Bethlehem Steel Corp. In June, the *Roger Blough* of about 45,000-ton cargo capacity was placed in service by United States Steel Corp. The cargo capacity of each vessel was more than 50% greater than the largest carriers previously operated on the lakes. The vessels were used to transport iron ore pellets from Minnesota ports on Lake Superior to steelworks on the south shore of Lake Michigan. These two vessels transported a combined total of more than 3 million tons of pellets during the 1972 shipping season.

Several of the existing lake carriers were being lengthened to increase cargo capacity. The capacity of two vessels was each increased by 15% to about 30,000 tons in 1972, and similar modifications were planned for two smaller vessels during 1973.

Efforts to extend the lake shipping season were again successful in 1972. With increased icebreaker support, bubbler systems to eliminate channel ice, and other navigational aids, ore shipments continued until December 29 from Silver Bay, Minn., until January 1 from Superior, Wis., and until February 7, 1973, from Two Harbors, Minn. The number of vessels loaded at each U.S. port, the total tonnage shipped, and average size of cargo in the 1972 shipping season are shown in the following tabulation. The larger average cargo shipped from Two Harbors and Taconite Harbor, Minn., in 1972 was due to loadings of the two large carriers mentioned above.

Lake shipping port	Number of vessels loaded	Total tonnage shipped [1] (thousand long tons)	Long tons [2]	
			Average cargo	Largest cargo
Duluth, Minn	956	14,866	15,500	27,500
Taconite Harbor, Minn	463	10,600	22,900	55,800
Superior, Wis	559	10,172	18,200	NA
Silver Bay, Minn	547	9,481	17,300	27,700
Escanaba, Mich	596	9,357	15,700	27,300
Two Harbors, Minn	379	6,576	17,400	44,700
Marquette, Mich	183	3,062	16,700	25,200
Total	3,683	64,114	17,400	XX

NA Not available. XX Not applicable.

[2] Rounded to nearest 100 tons.

Source: Skillings' Mining Review. various issues, 1972–73.

Published freight rates for rail and vessel transport of iron ore from Lake Superior district mines to consuming centers, and dock-handling charges, in effect on April 15, 1972, were unchanged from those in effect 1 year earlier.[2] As noted in the section on prices, however, the bulk vessel freight rate for iron ore was actually increased by 12 cents per gross ton in February 1972, a rise of about 5% compared with the 1971 rate. After the close of the 1972 shipping season, new rates for rail and lake freight, and dock handling charges and storage costs at lower lake ports, were announced prior to the start of the 1973 shipping season. The cost of rail freight increased 4% to 6%, lake freight by 4%, dock handling charge at lower lake ports by 5% to 6%, and the dock storage charge at lower lake ports rose 20% (to 3 cents per ton).

In oceanborne iron ore trade, freight rates increased during 1972. The low rates prevailing late in 1971 continued over into the early months of 1972, but the Japanese seamen's strike which lasted from April to mid-July, and very large grain-shipping contracts negotiated by the United States with the Soviet Union and other countries during the spring and summer, reduced the number of ships available to the iron ore trade and helped to drive up freight rates during the last half of the year. By yearend, freight rates from the principal iron ore exporting countries to consuming centers in North America, West Europe, and Japan were about double those in the spring, and indications were that the rates would rise further in 1973. Some rates for individual shipments in 1972 reported by various issues of Metal Bulletin were as follows:

---

[2] University of Minnesota Bulletin. Mining Directory Issue 1972, table 14.

Country and port	Destination	Tonnage of shipment	Rate per ton	
			Early 1972	Late 1972
Angola (Port Salazar)	West Europe	45,000–50,000	$2.15 (Dunkirk)	$4.00 (West Italy)
Australia (Dampier)	Belgium	50,000–60,000	3.25	6.50–6.80
Australia (Port Hedland)	Port Talbot or Amsterdam.	80,000–100,000	[e] 2.60 (Oct.–Nov. 1971)	4.62–6.00
Brazil (Tubarão)	Western Europe	50,000–70,000	2.00–2.15	4.00–4.85
Do	Japan	70,000–100,000	3.20–3.30	5.65
Do	Eastern United States	30,000–43,000	1.90 (Dec. 1971)	4.87 (Jan. 1973)
Canada (Sept-Îles)	United Kingdom, Italy, Netherlands.	50,000	1.30–1.80	3.25–3.45
Chile [1]	Japan	46,000–62,000	3.10	6.90
Liberia (Monrovia)	Netherlands	40,000–70,000	1.40	2.60
Mauritania (Port Etienne)	United Kingdom	22,000	2.50	3.50
Norway (Narvik)	United Kingdom	15,000	.75 (Port Talbot)	[e] 2.60 (Middlesbro)

[e] Estimate.

[1] Port not specified.

By the end of 1972, an estimated 11 foreign ports, two more than in 1971, were capable of loading iron ore carriers of 100,000 to 175,000 deadweight tons (d.w.t.). The number was expected to increase to 13 in 1973, with completion of a new port at Sepetiba Bay, Brazil, and expansion of facilities at Narvik, Norway. In 1973, three ports (Sept-Iles, Tubarão, and Sepetiba Bay) will be capable of loading carriers of 250,000 d.w.t. and a similar capacity was expected to be developed at Narvik by 1974.

At consuming centers, 13 foreign ports were capable of accommodating iron ore carriers of 100,000 to 150,000 d.w.t. in 1972. Nine of these were located at steelworks in Japan and the others were located in western Europe (Rotterdam, Amsterdam, Port Talbot, and Taranto). In Japan, the sea berth for the Oita works of Nippon Steel Corp. was expected to accommodate carriers of up to 300,000 d.w.t. in 1973. In the United Kingdom, where, except at Port Talbot, ore carriers of only about 20,000-35,000 d.w.t. could be accommodated, a new terminal at Immingham was completed in 1972 and the Redcar terminal at Teesside will be completed in 1973. These new facilities will initially permit berthing of 65,000 d.w.t. vessels at Immingham and 150,000 d.w.t. vessels at Teesside. In the United States, relatively shallow channel depths limited the size of incoming iron ore cargoes to a maximum of about 65,000 tons although cargoes of up to 80,000 tons were formerly exported from the port of Long Beach. New port facilities being constructed at the Sparrows Point, Maryland works of Bethlehem Steel Corp. in 1972 may permit berthing of 100,000 d.w.t. carriers in 1974 if the necessary channels are provided.

Slurry transport of iron ore increased in 1972. An estimated 1.3 million tons were shipped in special carriers to Japan, mainly from New Zealand and Peru. The largest single cargo reported during the year was 80,000 long dry tons. In overland transport, slurry pipelines of 20 to 30 miles in length are scheduled to be built for iron ore projects in Argentina and Mexico, and a feasibility study was being made for a proposed 200-mile pipeline in the Republic of South Africa.

Data on ocean shipments of iron ore from some foreign ports in 1972 are shown in the following tabulation, which may be compared with data shown for U.S. lake shipments.

Ocean shipping port	Number of vessels loaded	Total tonnage shipped (thousand long tons)	Long tons	
			Average cargo	Largest cargo
Tubarão, Brazil	431	27,864	64,600	166,000
Port Hedland, Australia [1]	[2] 412	[2] 25,605	[e] [2] 62,000	132,300
Dampier, Australia	288	22,117	76,800	159,300
Narvik, Norway [3]	[e] 530	20,175	[e] 38,000	85,600
Kirkenes, Norway [4]	100	2,541	25,800	[e] 135,000
Puerto Ordaz, Venezuela	375	14,550	39,000	NA
Sept-Îles, Canada	447	13,609	30,000	[2] 137,000
Buchanan, Liberia	215	11,147	51,800	NA
Mormugao, India	NA	11,107	NA	[e] 30,000
San Nicolas, Peru	136	8,900	65,000	142,000
Port Cartier, Canada	257	7,432	29,000	[2] 135,000
Porto Salazar, Angola	NA	4,967	NA	144,000
Guacolda, Chile	42	2,872	68,000	93,000

FOREIGN TRADE

U.S. exports of iron ore in 1972 declined by 32% compared with those of 1971 and were the lowest since 1946. The reduction was mainly due to expiration of a long-term contract between the Mitsubishi Corp. of Japan and Kaiser Steel Corp. Shipments of ore to Japan from Kaiser's Eagle Mountain mine were terminated in December 1971. Exports of ore from California to Japan by the Standard Slag Corp. were expected to continue through 1975 at the rate of about 500,000 tons annually, under a contract expiring in 1976. About two-thirds of U.S. exports in 1972 went to Canada, mostly from ports on the Great Lakes.

U.S. imports of iron ore for consumption also declined in 1972 and were the lowest since 1963. The low volume of imports was mainly due to large inventories of ore at U.S. consuming plants and to relatively low demand for steel in the first half of the year. Imports of ore from Canada, which were reduced to some extent by strikes at some Canadian mines and ports, declined by 2.2 million tons, and imports from Venezuela declined by 2 million tons compared with those of 1971. Imports from Liberia and Peru increased, but imports from Australia and Brazil were down by more than 30% and imports from Chile dropped by 65% compared with the previous year.

In 1972 the average value of iron ore exports was $12.78 per long ton, compared with $12.46 in 1971, and the average value of imports was $11.63, compared with $11.23 in the previous year.

WORLD REVIEW

Argentina.—Late in 1972, financing was obtained for construction of concentrating, pelletizing, and transportation facilities for the Sierra Grande iron deposits in Rio Negro province. Loans granted to Hierro Patagonica de Sierra Grande, S.A., a Government-controlled company, included $20 million from the Canadian Export-Import Bank and $32 million from the Inter-American Development Bank.

A concentrator will be built at the mine site by 1975 by a Japanese group including the Mitsubishi Co. and Kurimoto Iron Works Ltd. Using magnetic separation and flotation processes, the plant will be capable of producing 2 million tons of iron concentrate (and possibly 200,000 tons of byproduct apatite concentrate) per year from 3.1 million tons of crude ore. A 30-kilometer pipeline will be built to carry iron-concentrate slurry to a pelletizing plant at Punta Colorada.

The pellet plant will be built by a group of companies headed by Wright Engineers Ltd. of Canada. The plant will employ the U.S. Midrex process although most of the equipment will be manufactured in Canada and Argentina.

Port facilities at Punta Colorada will be built by a group of German and Argentine firms, including Fried. Krupp G.m.b.H. of West Germany. The shipping distance from Punta Colorada to Buenos Aires is approximately 1,300 kilometers.

Argentine imports of iron ore totaled 1.59 million tons in 1971, more than twice the quantity imported in 1970. Domestic production of pellets from Sierra Grande is expected to substantially reduce Argentine import requirements, but in view of the Government's plans to double production of steel by 1980, the output from Sierra Grande may supply less than half of the country's ore requirements at that time.

Some barter agreements were made in 1972 by which Argentina would exchange steel and meat products for iron ore from Chile. Argentina also hoped to import iron ore from the Mutún deposits of Bolivia, but transportation continued to be a significant problem.

Australia.—Production and shipments of iron ore in 1972 were about 3% more than in 1971. Output from most producers was at relatively low levels in the first half of the year, partly due to reduced demand for ore in Australia, Japan, and other countries and partly to a 3-month strike by Japanese seamen. In some cases, shipments to Japanese consumers were less than the minimum quantities specified in contracts, and large stockpiles of ore accumulated at some Australian ports. In the latter part of the year, however, shipments increased and a total of 64 million long tons was recorded for 1972. Exports of iron ore totaled were estimated at 52 million tons. The average iron content of Australian ore produced in 1972 was 63.6%.

Production capacity continued to increase. The Robe River project was completed in 1972; the first shipment of sinter feed was made in October, and shipment of pellets began by December. Hamersley Iron Pty. Ltd. expected to complete the Paraburdoo project by yearend; Goldsworthy Mining Ltd. was completing a 40-mile railroad and other facilities to bring the Shay Gap and Sunrise Hill ore bodies into production; and Mt. Newman Mining Co. Pty. Ltd. was also expanding capacity. Australian production capacity for iron ore was probably at least 95 million tons annually by yearend.

Production of iron ore pellets in 1972 was 6.3 million tons, compared with 6.7 million tons in 1971. Completion of the Robe River project increased Australian production capacity for pellets to approximately 11 million tons annually at the end of 1972. The Hamersley company planned to increase pellet capacity by another 600,000 tons annually by mid-1974.

Port facilities at Dampier and Port Hedland were also expanded in 1972, to speed up loading operations and to accommodate ore carriers of up to 150,000 d.w.t. The new port completed at Cape Lambert can also handle 150,000-ton vessels. The largest iron ore cargoes loaded during 1972 at Port Hedland and Dampier were 132,314 long tons and 159,281 long tons, respectively. The largest cargo loaded at either port in 1971 was 111,499 tons.

Exploration of "Mining Area C," about 200 miles south of Port Hedland, was continued by the Goldworthy Co. in 1972. Cyprus Mines Corp., which owns a one-third interest in the company, reported that proven ore reserves in this area exceeded 700 million tons, containing 63% iron.

Devaluation of the U.S. dollar and revaluation of Australian currency were matters of increasing concern to Australian iron ore producers, because the export price of most Australian ore is fixed in U.S. dollars in long-term contracts negotiated with Japanese buyers prior to 1971. Negotiations for upward revisions of these prices were expected to continue in 1973.

Iron ore shipments by Australian producers in 1971 and 1972, in thousand long tons, were reported[3] as follows:

Producer	1971	1972
Hamersley Iron Pty. Ltd	20,719	22,117
Mt. Newman Mining Co. Pty. Ltd	18,708	21,443
Goldsworthy Mining Ltd	6,897	6,465
Broken Hill Pty. Co. Ltd	12,114	8,891
Savage River Mines	2,193	2,806
Cliffs Robe River Iron Associates	--	1,369
Frances Creek Iron Mining Corp	949	823
Western Mining Corp. Ltd	649	610
Total	62,229	64,024

Brazil.—Production and exports of iron ore totaled about 41.4 and 30.8 million long tons, respectively, in 1972. The average iron content of ore produced was reported to be 65%.

---

[3] Skillings' Mining Review. Various issues, 1972 and 1973.

Production and exports were expected to increase substantially in 1973. Iron ore shipments by Companhia Vale do Rio Doce (CVRD), including shipments for associated companies, were expected to increase to 40 million tons compared with 30.2 million tons in 1972. Minerações Brasileiras Reunidas S.A. (MBR), which shipped 1.5 million tons from three mines near Belo Horizonte in 1972, will begin shipping ore from the Aguas Claras mine in the latter part of 1973. The latter mine will have an initial production capacity of 11.5 million tons annually. Under long-term contracts with Japanese buyers, the combined tonnage of ore scheduled for shipment to Japan by CVRD and MBR in 1973 was 5 million tons more than in 1972. Brazil was expected to become Japan's second largest supplier of iron ore in 1974.

The planned increase in CVRD shipments in 1973 was expected to come mostly from the Piçarrão mine which was opened in mid-1972, plus high-grade fines produced by the new concentrator at the Cauê mine, and increased output from associated companies. At yearend 1972, 14 of 26 concentrating lines were reported to be operating at the Cauê concentrator and the rest were scheduled for completion in 1973. The concentrator will process 20 million tons of crude ore annually by washing and high intensity wet magnetic separation to produce 9 million tons of sinter feed and 5 million tons of pellet feed.

CVRD's second pelletizing plant will be completed at Tubarão in early 1973. The plant's production capacity will be 3 million tons of pellets per year. CVRD shipped 1.9 million tons of pellets in 1972, including 1.3 million tons for export.

Development of iron ore shipping facilities at Tubarão (CVRD) and Guaiba Island (Sepetiba Bay) (MBR) were expected to permit berthing of 250,000 d.w.t. vessels at each port by late 1973. Export shipments from Tubarão in 1972 totaled 27.6 million long tons; the average cargo was 67,000 tons and the largest was 166,000 tons.

Exploration of the Serra dos Carajas iron deposits in Pará was reported by the Ministry of Mines and Energy to have proved reserves of 1.6 billion tons of ore averaging 67% iron. In addition, indicated reserves of 2.9 billion tons and inferred reserves of 6.6 billion tons were announced. A preliminary engineering study of the feasibility of exploiting the deposits was expected to be completed in 1972. The exploration company, Amazônia Mineração S.A., is owned 51% by CVRD and 49% by Cia. Meridional de Mineração, a subsidiary of United States Steel Corp.

Canada.—Total shipments of iron ore (including byproduct ore) in 1972 declined 8.7% compared with those in 1971. Exports declined by 12%, to 29.6 million long tons. The reductions were partly due to low export demand and the Japanese shipping strike in the first half of the year, but they were mainly due to Canadian strikes which halted operations at mines and plants in Labrador and northern Quebec for 2 to 3 months in the summer. Ore shipments from stockpiles at Sept-Îles and Pointe Noire continued for most of the strike period, as did construction of the Mt. Wright project and new concentration and port facilities at Sept-Îles, but expansion of the concentrator at Labrador City and completion of flotation and pelletizing facilities at Sept-Îles was not expected until 1973. The latter plants will increase annual production capacity of the Iron Ore Co. of Canada by 11 million tons of concentrates at Labrador City and by 6 million tons of pellets at Sept-Îles.

The Mt. Wright project of Quebec Cartier Mining Co. (QCM) was expected to be completed on schedule in 1975. Construction of the 75-mile railroad from Lac Jeannine, the new town of Fermont 12 miles northeast of Mt. Wright, and the concentrator buildings at the mine site were well underway by September. By the time that Mt. Wright comes into production, ore reserves at Lac Jeannine are expected to be depleted so that annual production capacity of QCM will be about 16 million tons of concentrates in 1976. It was possible that the Fire Lake iron deposits north of Lac Jeannine may also be developed for production, in which case the Fire Lake ore would probably be processed at Lac Jeannine.

Iron ore shipments from British Columbia were curtailed in 1972 by the Japanese shipping strike. Accumulation of concentrate stockpiles forced Wesfrob Mines Ltd. to cease mine production temporarily in July. Shipments of concentrates by Texada Mines Ltd. were unaffected, however, because the company operates its own ore carrier.

Two producers of byproduct ore, Cominco Ltd. and the Sudbury pyrrhotite plant of Falconbridge Nickel Mines Ltd., ceased production in 1972. Falconbridge also announced plans to close its direct-reduction plant at Sudbury in early 1973. The latter plant had an annual production capacity of 300,000 tons of metallized pellets containing about 92% iron and 1.5% nickel; shipments of pellets were reported to be 29,000 tons in 1972. Also at Sudbury, International Nickel Co. of Canada Ltd. canceled its projected 250,000-ton expansion of iron ore pelletizing capacity because of new antipollution regulations. At Contrecoeur, Quebec, Midland-Ross Corp. was building a prereduction plant for production of 400,000 tons of metallized pellets per year. The plant was being built for the Siderurgie Quebec (Sidbec) and Dominion Steel and Coal Corp.) (Dosco) interests, and was scheduled for completion early in 1973.

Canadian consumption of iron ore was estimated at 11.6 million long tons in 1972, up from 10.8 million tons in 1971. Canadian production capacity for iron ore at yearend was 47.35 million tons annually, including 25 million tons of pellets. Total capacity late in 1973 was expected to be about 60 million tons.

Chile.—Production of iron ore in 1972 was 23% less than in 1971, and exports may have declined even more. The declines appeared to be due to sharply reduced demand for Chilean ore in Japan and the United States in 1972. Imports of iron ore from Chile in 1972, as reported by Japan and the United States, totaled 6.9 million long tons, nearly 30% less than in 1971. Chile exported 10.14 million long tons of iron ore in 1971, of which 98% was destined for Japan and the United States.

The El Laco mine, in northeastern Chile 20 miles from the Argentine border, was expected to begin production early in 1973. No further details were available.

European Economic Community (EEC).—Production of iron ore in the EEC countries declined in 1972, but imports increased and overall consumption of iron ore rose about 7% compared with 1971. Imports of iron ore totaled about 96 million long tons, of which 78 million tons came from foreign sources (principally Sweden, Liberia, and Brazil) and 18 million tons came from France.

Some statistics on consumption of iron ore in the EEC are shown in table 2.

During the 3-year period 1970–72, production of crude and marketable ore in the EEC declined about 7% while total employment declined 14%. During this period, average output of crude ore per man-shift in underground mines rose about 25% in West Germany, 14% in France, 39% in Luxembourg, and 68% in Italy; in open pits, average productivity increased 23% in the eastern (Lorraine) region of France but declined 25% in Luxembourg. Some statistics on the EEC iron mining industry in 1972 are shown in table 3.

Production capacity for crude iron ore in the EEC was estimated at 72.0 million long tons per year in 1972, compared with 103.8 million tons in 1962. Output capacity in 1975 was expected to be 74.3 million long tons.[4]

[1] Total figures exceed sum of individual countries listed; difference may represent data for Belgium.

[2] Including ore shipped to other EEC countries. French shipments included 35.9 million tons to domestic industry and 18.3 million tons to other EEC countries, principally Belgium and Luxembourg.

[3] Mostly crude ore.

[4] Not including apprentices or salaried personnel.

[5] Including 8,848 underground workers, 330 open pit workers, 4,331 other surface workers, 87 apprentices, and 2,766 salaried personnel.

[6] In the eastern mines, which account for about 95% of total French output, productivity figures were 40.7 for underground mines and 266.0 for open pit mines. Corresponding figures for western mines were 17.4 and 11.3, respectively.

[7] As of October 1972. Includes apprentices. U.S. dollar equivalents based on spot exchange rates in each country at end of 3d quarter 1972 (Source OECD (Paris). Principal Economic Indicators. December 1972, pp. 68–90).

[8] Eastern mines only.

Principal source: Statistical Office of the European Communities (Luxembourg). Iron and Steel, Bimonthly Statistics. No. 1, 1973, pp. 182–191. (Source reports quantities in metric tons.)

Finland.—Construction of the concentrator for the Rautavaara underground iron mine near Kolari was started in 1972. The plant was expected to begin production in 1974 at the rate of 400,000 to 500,000 tons of magnetite concentrate per year. The concentrate will be sent to the State Steelworks at Raahe.

Production of iron ore from the Leveäselkä deposit near Raajärvi began in 1972. The ore was concentrated at the Raajärvi plant.

An agreement between the Governments of Finland and the Soviet Union, for joint development of iron deposits in the Kostomus area of Soviet Karelia, was likely to be signed in 1973. The Finnish Ministry of Transport reportedly began engineering studies for a 37-mile railroad line between Kontiomaki and the Soviet border in 1972. If the proposed Kostomus project is carried out, production of concentrates (possibly pelletized) would probably begin sometime after 1976. Part of the output would be consumed in Finland and part would be exported from Finnish ports. Imports of iron ore by Finland amounted to 771,000 tons in 1972, but ore requirements are expected to increase by about 1 million tons per year in 1976 when the new blast furnace at Raahe is scheduled to begin production.

Gabon, Guinea, and Ivory Coast.—The possibility of exploiting deposits of iron ore in these countries continued to be investigated in 1972, but owing to the difficulty in obtaining the necessary financing no firm plans for development were announced by yearend. In Gabon, development of the Bélinga deposits, which reportedly contain more than 500 million tons of proved ore averaging 64% Fe and 0.12% phosphorus, would require construction of a 350-mile railroad in addition to port and mine facilities. In Guinea, exploitation of the Nimba and Simandou deposits would require construction of a 450-mile railroad and port facilities if the Government decides that the ore should be transported wholly within Guinea, but since the Nimba deposits (potentially, 200 million tons averaging 47% Fe) lie within 20 miles of already-established ore-hauling railroad in Liberia, these might be developed if the necessary agreements can be worked out between the Governments of the two countries and the Liberian-American-Swedish Minerals Co. (LAMCO), which operates the Liberian railroad, to transport the ore to Buchanan. Simandou deposits, about

50 miles north of Nimba, contain about 350 million tons of potential reserves averaging 64% iron. In Ivory Coast, development of low-grade iron deposits at Mount Khowayo, about 60 kilometers east of the Liberian border, would require construction of a 150-mile railroad (or pipeline), port facilities, and beneficiating and pelletizing plants. Large reserves reportedly occur in the Khowayo area, averaging between 35% and 40% iron.

India.—Production and exports of iron ore in 1972 increased by 2% and 5%, respectively, compared with those of 1971. Exports in 1972 totaled 21.14 million long tons, of which 83% was destined for Japan. Domestic consumption of iron ore was reported at 10.7 million long tons, up 2% from 1971.

Expansion of production and transportation facilities continued to be slow, but government plans to increase exports to 51.0 million long tons in 1975 were unchanged from the previous year. To achieve this level of exports, the outloading capacity of Indian ports will have to be more than twice the estimated total capacity in 1972 (24.3 million tons) and nearly 50% more than the total capacity planned by the end of 1974 (34.6 million tons). An additional 4-million-ton increase in exports may be realized if the Kudremukh project and its slurry pipeline were built, but government approval for the project had not been received by yearend. In 1972, India continued to rank second to Australia in exports of iron ore to Japan, but Brazil was expected to become Japan's second largest supplier in 1974.

Expansion of the Bailadila mine, to a productive capacity of 10 million tons annually by 1976, was reportedly on schedule in 1972 but expansion of the Kiriburu mine was delayed. Annual production capacity in 1972 was 4 million tons at Bailadila and 3.3 million tons at Kiriburu. The pelletizing plant constructed by Tata Iron and Steel Co. Ltd. at Noamundi, with a production capacity of 1 million tons annually, was reported to be in production by the end of 1972. In Goa, pelletizing facilities of Chowgule and Co. Ltd. were reportedly expanded in 1972, but shipments of pellets (485,000 tons) were about the same as in previous years.

Japan.—Imports of iron ore by Japan in 1972 exceeded 100 million tons for the third straight year. Imports in 1972 totaled 110 million long tons (113 million tons in 1971), with Australia and India supplying 43% and 16%, respectively. Supplies from other countries, as reported in Japanese trade statistics, included (in million long tons) 9.2 from Brazil, 6.8 from Peru, 6.6 from Chile, and more than 2 million tons each from six other countries. Imports of iron concentrates produced from beach sand deposits in New Zealand, Indonesia, and Panama totaled 1.4 million tons, although the actual total may have exceeded 2 million tons due to imports of similar ores from the Philippines.

Domestic production of iron ore pellets was 3.86 million long tons, compared with 4.17 million tons in 1971. Domestic supplies of pellets totaled 14.2 million tons in 1972, including 10.3 million tons of purchased pellets which were probably mostly obtained from Australia and Peru. Consumption of foreign and domestic iron ores in 1972, as reported by the Japan Iron and Steel Federation, totaled approximately 117.4 million long tons, including iron ore (93.2), foreign pellets (9.0), iron sands (2.9), ferruginous manganese ore (1.3), pyrite cinder (0.5), and "other" (domestic) materials (10.5). "Other" material may consist mainly of plant dust and scale, and domestically produced pellets.

New pelletizing plants under construction in 1972 were expected to increase Japanese production capacity for pellets to about 9 million tons annually by early 1973. At the Kakogawa Works of Kobe Steel Corp., a new plant with annual output capacity of 2 million tons was reportedly operating by the end of 1972. At the Hirohata Works of Nippon Steel Corp., a 2.5-million-ton plant was scheduled for completion in January 1973. Part of the feed to the Hirohata plant was to be iron ore concentrates shipped in slurry form from Peru. At the Mizushima Works of Kawasaki Steel Corp., a $10 million plant for pelletizing 1,000 tons per day of in-plant dust and sludge was scheduled for completion in March 1973. Pellets produced by the latter plant were expected to contain about 75% iron. Kawasaki was also reported[5] to have closed the last remaining pellet plant at the company's Chiba Works, where a new 7,000-ton-per-day sinter plant was under construction. Total production capacity of the three pellet plants closed at Chiba since November 1969 was about 1.7 million tons per year.

---

[5] Metal Bulletin (London). No. 5679, Feb. 29, 1972, p. 26.

Liberia.—Production of iron ore in 1972 was approximately the same as the previous year, but production of iron ore pellets increased 19%, and total exports increased nearly 10% to 22.4 million long tons. The increased output of pellets was due to the first full year of production at the Bong Mining Co. plant. Of total Liberian production in 1972, lump ore comprised 22%, pellets 16%, and the remainder consisted of fines.

Of total exports, shipments by LAMCO accounted for about 50%; Bong Mining Co., 24%; National Iron Ore Co., (NIOC) 17%; and Liberia Mining Co. (LMC) for the remainder. Seventy-one percent of the exports was destined for EEC countries, principally West Germany and Italy. About 2.5 million tons each went to the United States and Japan. The average cargo shipped from Buchanan in 1972 by LAMCO was 52,000 tons, while at Monrovia, the average was 53,000 tons for Bong and 33,000 tons for NIOC.

LAMCO's mining project at Mt. Tokadeh was completed in 1972 and the first shipment of concentrates was made shortly after the end of the year. Reserves of easily-concentrated ore at this property were stated to be about 100 million tons, averaging 53% iron. LAMCO expected to produce 12.1 million long tons of ore products in 1973, including 1 million tons from Mt. Tokadeh. The company continued explorations in the Mt. Tokadeh-Beeton-Yuelliton area, completing 6,000 feet of diamond-drilling and 2,900 feet of tunneling. A new crushing plant will be installed at Buchanan by early 1974, to reduce lump ore to 30 millimeters diameter.

The LMC ore body at Bomi Hills was expected to be exhausted by the end of 1973. LMC continued to explore deposits at Bie Mountain, 22 miles northwest of the Bomi mine.

NIOC continued to expand production capacity at Mano River, with completion of the Mano II project scheduled for early 1973. Total ore reserves were estimated by company officials in 1972 to be at least 200 million tons. An option to acquire control of the Wologisi iron deposits by a group of Japanese companies by May 1, 1972, was not exercised. No further developments were reported by yearend.

Malaysia.—Production of iron ore continued to fall rapidly. Output in 1972 was 45% less than in 1971, and it was possible that no ore would be mined in 1974 as no contracts for export to Japan were indicated beyond 1973. Practically all Malaysian output has been exported to Japan. Exports to Japan in 1972 were estimated at 350,000 tons, and the only reported contract for 1973 was for 180,000 tons from the Sungueygau mine of Sharnkat Brimca Mining Co. Ltd.

Mexico.—Contracts for construction of two pellet plants were signed in 1972. Arthur G. McKee & Co. of Cleveland will design and construct a circular-grate pelletizing plant at the La Perla mine in Chihuahua for Altos Hornos de Mexico S.A. Production capacity of the plant will be 600,000 tons of pellets per year, with completion scheduled by the spring of 1974.

Consorcio Minero Peña Colorada S.A. contracted with Lurgi Chemie und Hüttentechnik G.m.b.H. for construction of a pellet plant at Manzanillo on the west coast. Production capacity of the plant will be 1.5 million tons of pellets per year beginning in 1974. Ore feed for the plant was to be supplied by a 30-mile slurry pipeline from mines in Colima.

Shipments of pellets in 1972 by Las Encinas S.A. totaled 1.29 million long tons, 50% more than shipments in 1971. About 75% of shipments in 1972 went to the Monterrey and Puebla plants of Hojalata y Lámina S.A. and the remainder to Tubos de Acero de Mexico, S.A. in Vera Cruz. Shipments of iron ore in 1972 by La Perla Minas de Fierro S.A. and Cía Fundidora de Fierro y Acero de Monterrey S.A. totaled 3.09 million long tons.

Morocco.—Production of iron ore in 1972 was 62% less than in 1971. Most of the output was reportedly stockpiled, as preparations were made to begin processing the ore in the new Uixan concentrator and pelletizing plant which have been under construction since 1970. Production of iron ore pellets, at an annual rate of about 850,000 tons, was expected to start during 1973. Concentration of the magnetite ore is expected to yield about 80,000 tons of byproduct pyrite per year.

Exports of iron ore in 1972 totaled about 325,000 long tons, mostly destined for West Germany and Czechoslovakia.

An agreement settling the border dispute between Morocco and Algeria and providing for joint exploitation of iron deposits at Gara-Djebilet was reportedly signed June 15, 1972, by the Governments of both countries. The Gara-Djebilet deposits are located 130 kilometers southeast of Tindouf, Algeria.

New Zealand.—The sharp increase in production of iron ore in 1972 was due to the first full year of production at the Waipipi iron-sand project on the west coast of North Island. Shipments of titaniferous magnetite concentrate from the Waipipi operation totaled 942,000 tons in 1972. All of the concentrate was shipped in the form of slurry, using the Marconaflo system. The Waipipi project is operated and 75% owned by the Marcona Corp. Reserves of beach sand, averaging about 11% iron, reportedly totaled more than 300 million tons at the end of 1972.

Norway.—Exports of iron ore in 1972 totaled about 2.9 million long tons including 1.2 million tons of pellets. The principal destinations continued to be West Germany and the United Kingdom. A/S Sydvaranger, the major Norwegian producer, increased shipments to more than 2.5 million tons but prices were reportedly lower than in 1971.

Construction of a second pelletizing line was begun by A/S Sydvaranger at Kirkenes in 1972. Completion of this project will increase the company's production capacity for pellets to about 2.7 million tons per year by the end of 1974. The company contracted with the British Steel Corporation to deliver 6 million tons of pellets during a 6-year period beginning in 1973.

Shipping capacity for iron ore at the ports of Kirkenes and Narvik was increasing in 1972. At Kirkenes, two vessel cargoes of 137,500 tons each were loaded during the year; the largest ship previously accommodated was about 75,000 d.w.t. At Narvik, which is the main shipping port for Swedish iron ore, the largest single cargo loaded in 1972 was about to be 86,000 long tons. The port was being developed to accommodate vessels of up to 300,000 d.w.t. by 1975.

Panama.—Production of iron ore concentrates from Pacific beach sand deposits in the Balboa district may have begun late in 1971. The first shipment of concentrates was made in February 1972. The operating company, Hierro Panama S.A., was jointly owned by Sumitomo Shoji Kaisha Ltd. of Japan and Minera de Chame S.A. of Panama. A contract was negotiated by Sumitomo in 1970 for export to Japan of about 1.5 million tons of concentrate during a 6-year period.

The beach sand reserves were estimated to contain 2.5 million tons of concentrate averaging 62% to 63% Fe and about 7% TiO_2.

Peru.—Shipments of iron ore products in 1972 by Marcona Mining Co. totaled 9,096,000 long tons, of which 8,900,000 tons were exported and 196,000 tons were shipped for consumption in Peru. Total shipments included 3,335,000 tons of pellets and 382,000 tons of iron ore slurry plus filter cake. An estimated 75–80% of export shipments were destined for Japan. Vessel shipments to Japan included one cargo of 141,732 long tons, consisting of 96,525 tons of slurried pellet feed discharged at Hirohata and 45,207 tons of sinter feed unloaded at Oita. Total shipments of iron ore products from San Nicolas by Marcona reached the 100-million-ton mark in March 1971.

Late in 1972, a group of five Japanese steel companies contracted with Marcona for delivery of 22 million tons of iron ore pellets over a 7-year period beginning in 1975. The Japanese group will lend Marcona $66 million for construction of new pelletizing facilities which will have an initial production capacity of 3.5 million tons of pellets per year in 1975. Production capacity of the existing pellet plant at San Nicolas was raised to 4 million tons per year by early 1972.

Philippines.—Iron ore was produced by eight companies in 1972. Philippine Iron Mines, Inc., produced 32% of the total output from magnetite-hematite deposits in Luzon, where the product was processed for pelletizing and export by Pellet Corp. of the Philippines, a Japanese-owned company. Titaniferous magnetite concentrates, produced by four companies from beach sand deposits in Luzon and Leyte, accounted for 58% of total output, and most of the remaining 10% was byproduct magnetite produced by two companies from copper ore milling operations in Cebu and

Luzon. About 12,000 tons of lump ore were produced at the Sibuguey mine in Mindanao by Zambales Base Metals, Inc. The latter mine was closed in July 1972.

Exports of iron ore totaled 2.27 million dry long tons in 1972, 7% more than exports in 1971. Practically all exports were destined for Japan. Japanese contracts called for export of a similar quantity in 1973.

South Africa, Republic of.—Although a final decision was not made by the Government in 1972 to proceed with the Saldanha Bay iron ore export project, the Government-owned South African Iron and Steel Industrial Corp. (ISCOR) announced plans in midyear to expand productive capacity of the Sishen mine by 6.2 million tons annually by 1980. Tenders were also invited for construction of an ore-blending and loading plant at Sishen. Cost of the expansion was estimated at about $30 million.

The Saldanha Bay project would require construction of a 530-mile railroad to the Sishen mine, a deepwater port and loading facilities at an estimated total cost of about $600 million. As an alternative to the Saldanha project, private producers advocated expansion of existing railway haulage capacity to Port Elizabeth and construction of a bulk carrier terminal at St. Croix Island. Cost of this project was estimated to be less than half of that for the Saldanha scheme. The economic viability of either project appeared to depend to a large extent on long-term export contracts with Japanese importers of iron ore, but the necessary contracts had not been signed by yearend.

In other developments, Palabora Mining Co. Ltd. was considering increasing production of high-grade byproduct magnetite concentrate to 4 million tons annually. In October, the company contracted with the Bechtel Corp. to study the feasibility of transporting this quantity of concentrate by a 200-mile slurry pipeline to Lourenço Marques or Punta de Vela on the Mozambique coast. Palabora currently produces about 1 million tons of the concentrate annually, mostly for export to Japan but reportedly stockpiles an additional 4 million tons of rough concentrate at the mine site.

South African exports of iron ore in 1972 totaled 4,985,000 long tons, about 9% less than in 1971.

Sweden.—Compared with 1971, Swedish production of iron ore declined 3.6% in 1972 but exports increased 5.5% to 27.2 million long tons. Domestic shipments declined 8.6% to 4.09 million tons. Mine stocks of iron ore at yearend totaled approximately 8.7 million tons, an increase of 1.38 million tons from a year earlier. Due to the high level of stocks, production of ore in 1973 was not expected to increase appreciably from the 1972 level.

Of total exports, 59% was lump ore, 21% was unagglomerated fines, and the remainder consisted almost entirely of iron ore pellets. The principal destinations of export shipments continued to be West Germany, Belgium-Luxembourg, and the United Kingdom.

The average f.o.b. value of ore exported in 1972 increased less than 3% in terms of Swedish krona, compared with the average value in 1971, but because of devaluation of the U.S. dollar and revaluation of the krona since 1971, the increase in dollar terms amounted to more than 10%. This weakened the competitive position of Swedish ore, especially in the West European market, relative to Australian and other foreign ores for which contracts were based on dollar values. Also, the use of larger ore carriers was reducing transoceanic freight costs. Consequently, late in 1972, Swedish prices for 1973 deliveries were reduced 12% to 15% for high-phosphorus ores and 6% to 10% for other ores. Gränges AB reported an average reduction in price of 7% for 1973 deliveries.

Turkey.—Plants for concentrating and pelletizing iron ore from low-grade magnetite/hematite deposits in the Divriği area were expected to be completed in 1975. Cost of the project was estimated at about $30 million, including $14 million in foreign exchange. Planned annual rates of production were 1.6 million tons of concentrates averaging 63.5% iron, and about 1.2 million tons of pellets.

The Divriği mines currently produce about 1 million tons per year of direct-shipping magnetite ore which is shipped by rail to state-owned blast furnaces at Karabük. Most of the planned output of concentrate and pellets may be shipped to the Ereğli Steelworks on the Black Sea coast.

United Kingdom.—Domestic production of iron ore continued to decline in 1972. Output was 12% less than in 1971. Imports of iron ore in 1972 (17.08 million long tons) were slightly less than in the previous year, while consumption of iron ore was down 3%, to 26.1 million long tons. The share of domestic ore in total consumption in 1972 was 34.6% on a gross-weight basis, but because of its low iron content (average 28%), domestic ore was estimated to have supplied only about 20% of the total iron units in ore consumed. Canada and Sweden supplied a total of 43% of the iron ore imported in 1972, and another 37% was supplied by Brazil, Mauritania, Venezuela, and Australia. More than 1 million tons of iron ore were also imported from the U.S.S.R. in 1972.

A new iron ore import terminal at Immingham, and an ore-blending plant at Scunthorpe, were probably completed in 1972 by the British Steel Corp. (BSC). Both facilities were planned for completion in mid-1972, as part of the "Anchor" project of BSC to modernize and expand iron and steelmaking operations at Scunthorpe. Under the project, the blast-furnace burdens at Scunthorpe will be changed from domestic ore to mixed domestic and imported ore. Earlier, BSC had made an agreement with British Rail for hauling 6 million tons of iron ore per year from Immingham to Scunthorpe, a distance of 23 miles. The Immingham terminal was planned to initially accommodate ore carriers of 65,000 d.w.t.

BSC also continued construction of the $35 million Redcar iron ore terminal at Teesside. Completion was expected by March 1973. This terminal will accommodate ore carriers of up to 150,000 d.w.t. BSC also planned to go ahead with construction of an ore terminal at Hunterston on the Firth of Clyde in western Scotland. The Hunterston terminal was planned to initially accommodate 250,000 d.w.t. vessels.

U.S.S.R.—Soviet production of crude iron ore in 1972 was estimated at about 379 million long tons. This assumes a ratio of 1.85 tons of crude ore for each ton of usable ore produced. Soviet plans were to produce 250 million long tons of usable ore in 1975, from 470 million tons of crude ore. About 80% of all usable ore produced in 1972 came from open pit mines and 20% from underground mines. About two-thirds of the usable ore output was concentrate. Average iron content of usable ore was estimated to be 59%, compared with 56.7% in 1965.

Production of iron ore pellets in 1972 was not reported but may have exceeded 13.8 million long tons. Output in 1970 and 1971 was reported[6] to be 10.6 million metric tons and 13.5 million metric tons, respectively. In October 1972, the (British) Davey-Ashmore Group reported the commissioning of an iron ore pelletizing plant at Krivoy Rog in the Ukraine. The plant has an annual production capacity of about 4 million tons of pellets and is fueled by natural gas. The plant was designed by Lurgi Chemie und Hüttentechnik G.m.b.H. of West Germany.

Soviet exports of iron ore in 1972 totaled 37.8 million long tons, an increase of 1.9 million tons compared with exports in 1971. Most exports of iron ore were destined for Czechoslovakia, Poland, and other East European countries, but the United Kingdom, Italy, and Japan each reported receipts of more than 1 million tons and imports of 349,000 tons were reported by West Germany.

Venezuela.—Shipments of iron ore by Orinoco Mining Co. and Iron Mines Co. of Venezuela in 1972 totaled 16,256,000 long tons, nearly 15% less than shipments in 1971. Shipments by Orinoco were reduced by about 2 million tons while those from El Pao were down by 740,000 tons. All but about 8,000 tons were exported, mainly to the United States.

Expansion of beneficiation facilities at Puerto Ordaz by Orinoco Mining Co. was continued in 1972. The project was designed to expand iron ore shipments to about 23.2 million long tons per year by the end of 1973. The company's direct-reduction plant at Puerto Ordaz was still undergoing break-in operations in 1972.

Bethlehem Steel Corp. authorized construction of a new crushing and washing plant at the El Pao mine. The plant will have an annual production capacity of about 3.6 million long tons of beneficiated ore products.

TECHNOLOGY

The size and productive capacity of iron ore mining, processing, and handling equipment continued to increase in 1972. At large mining operations in the United States and elsewhere, the use of power shovels with bucket capacities of 10- to 14-cubic yards, rotary drills for 10- to 15-inch blastholes, and trucks of 100- to 150-ton haulage capacity was common although many units of smaller capacity were also in use. A 16-yard shovel was being evaluated on the eastern Mesabi range, as were trucks of 200-ton haulage capacity at the Minntac and Mt. Tom Price mines in Minnesota and Australia. At taconite operations on the Mesabi range, blasthole drilling at the Butler, National, and Minntac mines was done mainly by rotary drills, while jet-piercers were used principally at the Thunderbird, Erie, and Peter Mitchell mines. At underground mines in Pennsylvania (Grace) and Missouri (Pea Ridge), load-haul-dump units with bucket capacities of 5- to 8-cubic yards were in use. In the large underground mines in northern Sweden, trucks of 40- to 80-tons haulage capacity were used. Front-end loaders with 13-cubic-yard capacities were scheduled to be used at the Tilden (Michigan) and Mt. Wright (Quebec) mines which are now being developed.

In materials handling, the capacity of loading and unloading systems at iron ore shipping and receiving ports was also being increased to handle larger stockpiling requirements and to accommodate the larger ore carriers coming into service. Bucket-wheel stacker/reclaimers were being installed at many of these facilities. Traveling shiploaders with individual capacities of 6,000 to 8,000 long tons per hour (ltph) were installed or under construction at the ports of Sept-Îles, Dampier, Port Hedland, and Sepetiba Bay in 1972, and a slewing-boom loader with reported capacity of 16,000 ltph will be installed at Tubarão in 1973. The largest ship unloaders in the United States were being installed at the Sparrows Point plant of Bethlehem Steel Corp., where three traveling clamshell bucket unloaders will have a combined free-digging capacity of about 5,800 ltph. The unloaders were reportedly designed to service vessels of up to 160,000 d.w.t., and are integrated with two bucket-wheel stacker/reclaimers with 220-foot booms. Similar clamshell unloaders were under construction or being installed at the Chiba and Mizushima plants of Kawasaki Steel Corp. in Japan, and at the Taranto plant of Italsider S.p.A. in Italy for vessels up to 250,000 d.w.t.

In ore milling and concentration, installation of a fine-screening circuit in the Pea Ridge concentrator was reported by Meramec Mining Co. to have reduced the average silica content of pellets produced to less than 3%. Fine-screening was also reported to have increased production capacity by 10% at the Fairlane concentrator of Eveleth Taconite Co. Autogenous grinding mills to be installed in large concentrators now under construction include six 27-foot-diameter units at the Tilden project, six 32-foot-diameter units at the Mt. Wright project, and at least two 34-foot-diameter mills at the Carol Lake plant of the Iron Ore Co. of Canada. Flotation cells of 500-cubic-foot capacity were being installed at the Sept-Îles and Tilden concentrators. For the Tilden pelletizing plant, Allis Chalmers was building a rotary kiln 160 feet long and 25 feet in diameter, reportedly the largest of its type in the United States. In Brazil, the Cauê concentrator, which will use 26 Jones high-intensity magnetic separators, was 50% completed by yearend and will be in production by 1974. A Carpco high-intensity separator was reportedly being tested at the Wabush Mines concentrator in 1972.

The demand for pelletized iron ore continued to be strong. An estimated 14 million tons of new plant capacity was installed worldwide in 1972 and an estimated 16 million tons of additional capacity was scheduled for completion in 1973. The Robe River plant, which started production late in 1972, was believed to be the only major plant to pelletize goethite or limonitic ore; all other pellet plants, with the possible exception of a small plant at Skopje, Yugoslavia, use magnetite or hematite feed.

Interest in prereduced iron ore also remained high, but improvements in technology appeared to be needed before large-scale production could be realized. Production in some cases appeared to be well below the rated capacity of existing plants, and Falconbridge Nickel Mines Ltd. announced that its new Sudbury plant would be closed early in 1973. In Australia, production of metallized ore by the Hamersley Iron Pty. Ltd. was still in the pilot plant stage. However, Armco Steel Corp. completed its ore reduction plant at Houston, Tex., in 1972, and completion of a 400,000-ton-per-year plant at Contrecoeur, Quebec, by Midland-Ross Corp. was expected early in 1973.

The Bureau of Mines continued research on beneficiation of low-grade, nonmagnetic iron ores of the taconite type, partly to find more economic methods of concentration which may permit commercial development of additional low-grade resources in the Lake Superior region. Bureau research on Michigan ores of this type, in cooperation with the Cleveland-Cliffs Iron Co., was largely responsible for the Tilden project now under construction on the Marquette range. Research also continued on dephosphorization of calcareous iron ore, production of iron ore superconcentrates[7] and pellets,[8] metallization of pellets and direct reduction of iron ore,[9] and raising the iron content of, and pelletization, of blast- and steel-furnace dusts for recycling.[10] A paper on the development and use of blasting agents and slurries was also published.[11]

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Insofar as availability of sources permit, data in this table represent the nonduplicative sum of marketable iron ore, iron ore concentrates and iron ore agglomerates produced by each of the listed countries. Moreover, concentrate and agglomerates produced from imported ores are excluded, under the assumption that the ore from which they are produced has been credited as marketable ore in the country where it was mined.

[2] In addition to the countries listed, Cuba and North Vietnam may produce iron ore but definitive information on output, if any, is not available.

[3] Shipments, dry tons, including byproduct ore.

[4] Calculated from reported iron content assuming a grade of 60% iron.

[5] Includes byproduct ore.

[6] Nickeliferous iron ore.

[7] Includes magnetite concentrate, pelletized iron oxide (from pyrite sinter) and roasted pyrite (purple ore).

[8] Includes pyrite sinter, not separable from available sources.

[9] Excludes iron oxide pellets produced from pyrite sinter.

[10] Includes manganiferous iron ore as follows, in thousand long tons: 1970—53, 1971—47, 1972—41.

[11] Includes byproduct magnetite as follows in thousand long tons: 1970—1,936, 1971—2,193, 1972—2,952; and manganiferous iron ore (20% to 35% iron, 15% to 30% manganese) as follows in thousand long tons: 1970—368, 1971—179, 1972—100.

[12] Year beginning March 21 of that stated.

[13] Concentrates including concentrate derived from iron sand as follows in thousand long tons: 1970—701, 1971—581, 1972—539.

[14] Largely concentrates from magnetite-titanium sands.

Iron and Steel

By F. E. Brantley[1]

The iron and steel industry continued to recover during the first part of the year from its poor performance in 1971. Except for a brief midseason slump, this momentum was maintained for the remainder of the year and total raw steel[2] production was up 10.6% over that of 1971. Steel mill shipments increased almost 5 million tons, but were 2 million tons short of the record set in 1969. Returns on sales and investment again were among the lowest for any industry, and it was apparent that a number of problems needed to be resolved if this segment of the Nation's economy is to maintain a position of world leadership. The most pressing were as follows: Shortage of available capital for installation of more efficient steelmaking equipment and for expansion, limiting the increasing imports, rebuilding of export markets, pollution controls, rising costs of raw materials (particularly ferrous scrap), and the threat of energy shortages.

Extensions of voluntary steel import restraints were agreed to by Japan and the European Community (EC) countries. However, a number of other countries markedly increased shipments into the United States. Apparent consumption of steel products, adjusted for imports and exports, was up 4%.

Increased steel production was reported for all major producing countries of the world, and accompanied a general improvement in the world's economic situation. Total world raw steel production increased by 8 percent to 692 million short tons, and the U.S.S.R. increased its lead as the world's largest producer at 139 million tons. Japan was in third place, after the United States, with 107 million tons. Spain's production reached 10 million tons, a 23% increase over 1971 output.

---

[1] Physical scientist, Division of Ferrous Metals, Assistant Directorate—Mineral Supply.

[2] The term raw steel, as used by the American Iron and Steel Institute, includes ingots, steel castings, and continuously cast steel. It corresponds to the term crude steel as used by the United Nations.

[1] American Iron and Steel Institute. Includes ingots, continuous cast steel, and all other cast forms.
[2] Based on average production in 1967 as 100.
[3] Data not comparable for all years.

Price advances to keep pace with inflationary trends occurred for steel products in most sectors of the world market. In the free world, trends toward consolidation of plants, and company mergers to reduce costs were the effects of economic and technological developments. Continued increases in small electric-arc furnace steelplants were occurring also in many areas where limited production was desired.

U.S. merchant iron producers were reduced to five during the year, and ferrous foundries to approximately 1,900. The cost of pollution control equipment placed in operation by U.S. steelmakers during the year totaled $201.8 million, with an additional $336 million budgeted for 1973 and later. Total capital outlay for new facilities was $1.2 billion.

PRODUCTION AND SHIPMENTS OF PIG IRON

Domestic production of pig iron totaled 88.9 million tons in 1972, an increase of 7.5 million tons, or 9.2% more than that produced in 1971. Average production of pig iron per blast-furnace-day increased to 1,789.6 tons, compared with 1,654.3 tons in 1971, and 1,641.6 tons in 1970, according to the American Iron and Steel Institute (AISI). A total of 126 blast furnaces were in blast at the beginning of the year, including three that produced ferroalloys. At yearend the total number in blast had increased to 143, with two producing ferroalloys. There were 216 producing furnaces at the beginning of the year, and 214 at yearend, of which ten were being relined and one rebuilt.

Shipments of pig iron approximated total production for 1972. Yearend stocks at consumer and supplier plants were down 119,000 tons, 6.7% under those of 1971.

Metalliferous Materials Consumed in Blast Furnaces.—For each ton of pig iron produced in 1972, an average of 1.634 tons of metalliferous materials was consumed in the blast furnaces. Total net iron ore consumed in blast furnaces including agglomerates, was 137.9 million short tons. The total tonnage of iron ore including manganiferous ore, consumed by agglomerating plants at or near the blast furnaces in producing 39.6 million tons of agglomerates was 34.0 million tons. The remainder consisted of mill scale, coke, limestone, dolomite, and small amounts of other materials. Domestic pellets charged to the blast furnaces totaled 64.7 million tons, and sinter charged was 40.5 million tons. Pellets and other agglomerates from foreign sources added an additional 10.8 million tons.

Blast furnace oxygen consumption totaled 15.5 billion cubic feet according to the AISI, compared with 13.3 billion in 1971, and 13.5 billion cubic feet in 1970.

Data reported to the Bureau of Mines by the iron and steel industry showed that blast furnaces, through tuyere injection, consumed 22.8 billion cubic feet of natural gas, 4.3 billion cubic feet of coke oven gas, 183.1 million gallons of oil, and 67.5 milion gallons of tar, pitch, and miscellaneous fuel in 1972.

PRODUCTION AND SHIPMENTS OF STEEL

Domestic raw steel production edged slowly upward during the first half of the year, and although the 66.1 million tons produced in the first six months was below that for the same period in 1971, an increase during the last few months raised the year's total to 133.2 million tons. This was 12.8 million tons above the 1971 output, or an 8% increase.

The 1972 steel index, based on production in 1967 as 100, was 104.5, compared with 94.7 for 1971, and 103.4 for 1970. Of the total 1972 output, 56.0% was produced by the basic oxygen process (BOP), 26.2% by open-hearth furnaces, and 17.8% by electric furnaces.

Shipments of steel products for the year were up 5.5%, from 87.0 million tons in 1971 to 91.8 million tons in 1972. At yearend all signs pointed to a continuation of the sharp rate of increase evident during the last few months of the year. The largest markets were steel service centers and the automotive industry. Each accounted for over 18 million tons. Percentagewise, shipments by types of steel were approximately the same in 1972 as for 1971.

Materials Used in Steelmaking.—Metallics charged to domestic steel furnaces in 1972 per ton of steel produced averaged 1,246 pounds of pig iron, 1,103 pounds of scrap and 25 pounds of iron ore including agglomerates. In 1971 comparable amounts were 1,269 pounds of pig iron, 1,051 pounds of scrap, and 35 pounds of iron ore.

According to AISI, steelmaking furnaces consumed 531,100 tons of fluorspar, 2.2 million tons of limestone, 6.6 million tons of lime, and 1.1 million tons of other fluxes. Oxygen consumption by the iron and steel industry in steelmaking amounted to the equivalent of 189.5 billion cubic feet compared with 166.7 billion in 1971.

CONSUMPTION OF PIG IRON

Pig iron consumed in steelmaking totaled 83.57 million tons. Basic oxygen converters consumed 60.23 million tons; open hearths, 22.38 million tons; and electric furnaces, 0.96 million tons. An additional 2.66 million tons was consumed by iron foundries and miscellaneous users, primarily for charging cupola furnaces. Also, 2.9 million tons in the form of molten metal was used in making ingot molds and direct castings.

PRICES

Price increases previously announced by several companies for a variety of steel products, under authorization of the Federal Price Commission, went into effect January 1. Pricing during January was difficult to follow as various discounts and concessions were introduced by several companies in a short-lived price war. The finished steel composite price published by Iron Age decreased for February and remained stable for the rest of the year. Announcements were made by some companies that prices, in general, would be frozen for the rest of the year.

A widespread practice of distributor discounting on stainless sheet and coil caused a drop in composite prices of these items in June. This was followed in July by a stainless steel plate price increase of 5% by a few producers. Base price cuts of 20% for stainless plate had been previously announced by some mills in March. General tool steel raises were put into effect during the year. An increase of $3.35 per short ton for merchant pig iron also was posted by major producers during the year.

The composite price of pig iron, according to Iron Age, increased from $70.18 per short ton for January to $72.53 for December, and the composite price of finished steel went from $180.28 per ton for January to $179.76 for December. Comparable January and December prices, at Pittsburgh, for hot-rolled sheets were $172 and $167 per ton, and for cold-rolled sheets $185 and $202 per ton.

Price increases occurred in most major free world steel-producing countries during the year or were announced for 1973. West German producers applied in midyear to the European Communities Commission for increases averaging 4%, and Japanese steel export prices were reported to have risen by 15 to 20% during the year.

FOREIGN TRADE

The Voluntary Restraint Arrangement (VRA) limiting steel exports to the United States was regarded as basically successful for 1972. Participating countries—Japan, the United Kingdom, and the European Community—would limit for the 3-year period 1972–74, under terms expressed in letters of intent to the Secretary of State, the quantity of steel mill products exported to the United States. Both product mix and geographical mix was considered in limiting the shipments for each year. The 5% annual growth in the 1969–71 VRA was reduced to 2.5%, more in line with the historic pattern of the U.S. steel market increase. Japan also agreed to limit U.S. West Coast shipments to not more than one-third of total shipments. The terms were adhered to with few exceptions. There were differences in product classifications used by each country, also variations because of lag in times between export and import dates. The Japanese Minister of International Trade and Industry approved cartel arrangements for that country's steelmakers covering exports of various steel products to the United States for the year.

During the year, the legality of the VRA was challenged by the Consumers Union in a suit filed in the U.S. District Court for the District of Columbia. Prior to this suit, Japan had offered to reduce their 1973 exports to the U.S. West Coast to bring total shipments by both VRA participants and nonparticipants within the one-third limitation. Also during 1972, the Department of State had discussions relative to steel exports with several nonparticipating countries. These countries had increased shipments to the United States with resulting complaints by domestic producers, and efforts to obtain legislative relief.

Data compiled by AISI showed that imports of total steel products amounted to 18.3 million tons compared with 18.9 million in 1971. Steelmill product imports declined from the 1971 total of 18.3 million tons to 17.7 million tons. VRA participants accounted for 80% of the U.S. steel imports, compared with 84.3% in 1971, and total imports accounted for 16% of the domestic steel market, compared with 18% in 1971.

Exports of total steel products were essentially unchanged, 3.20 million tons for 1972 compared with 3.16 million tons in 1971. The chairman of AISI called for increased efforts to stimulate exports of steel from the United States to obtain a share of the increasing worldwide steel consumption.

WORLD REVIEW

Australia.—A preliminary proposal was submitted to the Commonwealth Government by the Government of Western Australia for an industrial complex in the Pilbara region. Costing $6.82 billion, the proposal included a steelworks with a capacity of 10 million tons per year. Major industries were expected to invest approximately 40% of the total amount, but at least one-half of the private industry development was to be home owned.

The 4-year expansion program at the Port Kembla steelworks of Australian Iron and Steel Proprietary Ltd. (Broken Hill subsidiary) continued. Completed in the third year of the program was a new blast furnace, and a steelmaking shop with two 225-ton oxygen converters. An article describing all phases of the new plant was published.[3]

An expansion program at the John Lysaght (Australia) Ltd. Westernport plant includes new mills and finishing facilities. Temporarily set back by labor difficulties, all units were expected to be in operation by 1974.

Canada.—Canada's steel industry had a record production year, with an increase of approximately 7% over the previous high in 1970. All major steel companies recorded increases, except Sydney Steel Corp. A labor strike there which lasted a month, also delayed the company's modernization program.

The Algoma Steel Corp. Ltd. was on schedule with its major construction jobs which included a new basic oxygen shop and a new blast furnace.

The Steel Co. of Canada Ltd. (STELCO) started the first phase of a $19 million expansion program at its Edmonton steelworks. Major new items would be two 75-ton electric arc furnaces and a continuous casting unit. STELCO also started a new $14.5 million electric furnace steelmaking plant at its McMaster works in Contrecoeur, to become operational by 1974. At the company's Hilton works in Hamilton three basic oxygen converters, a new bloom and billet mill, and a coke oven battery were brought on stream. These represented a total cost exceeding $160 million. STELCO also restarted its engineering studies on a new steel complex at Nanticocke, Ontario, on Lake Erie.

Dominion Foundries and Steel, Ltd. (DOFASCO) started up a new electrolytic tinning line and continued construction of equipment to control pollution problems.

---

[3] Pitt, R. S. Steelmaking at Port Kembla. Iron and Steel, v. 45, No. 5, October 1972, pp. 527–540.

Sidbec-Dosco Ltd., the New Government-owned integrated steel company, started its electric furnace steelplant at Contrecoeur and operated on scrap in 1972. The metallized pellet facility was expected to supply feed for the furnaces in 1973. Steel capacity of 600,000 tons per year was given.

Cominco Ltd. ceased operating its electric furnace pig iron and basic oxygen steelmaking facilities at Kimberley, British Columbia, since they were no longer considered to be economic.

Capital expenditures by the iron and steel industry, including foundries, in Canada were estimated at $431 million, compared with $427 million in 1971.

China, People's Republic of.—As part of China's expanding trade relations with the Western World, steel was one of the priority commodities in 1972. Chinese steel missions were active and several contracts were negotiated for the purchase of finished products. Contracts with Japanese steelmakers called for about 1.5 million tons to be delivered during the first half of 1973. Purchases were reported also from Australia and West Germany.

Interest in purchasing technology for the iron and steel industry as well as complete facilities was evident in reports from Japan. An official request for a firm bid was made of a Japanese firm and involved an estimated $300 million for hot and cold strip mills, a tinning line, a galvanizing line, and other mill equipment.

Steel production is expected to continue at a rate of increase approaching 10% per year. Demand was forecast as high as 42 million tons in 1975 according to Japanese studies. Present steelmaking capacity is indicated at 23 million tons, which includes 14 major works each having a capacity of over 1 million tons.

France.—There were four major steel projects in which activity was concentrated and which could be expected to influence the future steel position of France. These were:

1. The expansion at Dunkirk which would double the capacity of the Usinor steelworks. Included in the plans were a 10,000-ton-per-day blast furnace and a new oxygen steel plant. Production of raw steel would approach 9 million tons per year by 1975.

2. A new oxygen steel plant to be constructed as part of the Gandrange works at Orne-Aual by Sacilor, a subsidiary of the Wendel-Sidélor group. This with other construction, would be one of the centers around which the Lorraine steel industry would be based. Involved would be the closing of outdated plants and the regrouping of production in modern facilities.

3. Completion of the integrated steel complex at Fos. Usinor joined the Wendel-Sidélor group as a participant and a third partner was expected to share in the $1 billion undertaking. The first pig iron has been scheduled to be produced here early in 1974, with some rolling to take place in late 1973.

4. The expansion in specialty steel capacity was highlighted by plans for a new electric furnace works at Isbergues as a joint venture of Creusot-Loire and Châtillon-Commentry-Biache, and the Péchiney Ugine-Kuhlmann installation near Fos.

Under the sixth plan, the production targets set for 1975 would give France a maximum steel capacity by that date of approximately 35 million tons. This figure was based on an expected average annual rate of increase of 5% in the domestic steel market, and the deficit steel trade balances of recent years.

The Nation's steel companies numbered about 60 in 1972, with the top five producers accounting for three-fourths of total steel produced. Continued regroupings have occurred since 1947 when the steel industry numbered 122 companies. In recent years mergers, establishment of joint subsidiaries, and agreements between companies have been resorted to, in order to keep the French steel industry competitive. Increased expenditures scheduled for iron and steel research also are expected to be a factor in strengthening the industry.

Germany, Federal Republic of.—West German steelmakers slowly started to regain the position held prior to the slump which culminated in 1971, and resulted in 1971 being called one of the worst years on record. Raw steel production in 1972, 48.2 million tons, was still 1.5 million tons below that of 1970.

Capital investments continued high but were below the total for the previous year. With steel price increases lagging production cost increases, it was the general opinion that favorable profitability would not occur before 1973. The Thyssen Steel group, August Thyssen Hütte A. G. (ATH), Europe's largest steel producer, scheduled $217 million for capital spending in 1972 compared with $317 million the previous year. ATH's new blast furnace at Duisburg-Huckingen was completed. The group also set up a new company, Thyssen Purofer G.m.b.H., to further large-scale applications of its Purofer direct-reduction process. Thyssen Niederrhein, another new company of ATH, was to combine part of the group's special steel operations, including takeover of part of the operations formerly handled by ATH and Mannesmannröhren-Werke.

The new steel mill, Hamburger Stahlwerke G.m.b.H. (HSW), of the Korf group was officially inauguarated in April. The installation, built at a cost of $75.8 million, uses the Midland-Ross direct-reduction process, and has a capacity of approximately 600,000 tons per year. Klöeckner-Werke A. G. of West Germany planned to take a minority interest in HSW and receive the excess of continuously cast billets for its plant. It was estimated that HSW would increase raw steel production to 800,000 tons per year after the deal is concluded.

Th. Wuppermann G.m.b.H. was to install a new electric melting shop at Leverkusen with a capacity of approximately 500,000 tons per year. Scrap would be used initially as the charge material with partial use of prereduced pellets later.

Hoesch A. G. and Hoogovens of the Netherlands created a joint holding company, ESTEL N.V. (Hoesch-Hoogovens) in July at Arnhem. Raw steel capacity of the combine would be 12 million tons per year, third in Western Europe behind the British Steel Corp. and ATH.

Fried. Krupp Hüttenwerke A. G. became the first German producer of stainless steel using the argon-oxygen decarburization (AOD) method. The equipment was placed in operation at the firm's Bochum plant in August as part of its modernization program.

India.—Takeover of the Indian Iron and Steel Co. (IISCO) by the Government was approved by both Houses of Parliament for a period of 2 years. IISCO was the second largest steel producer in the private sector, but was reported to be in financial trouble and also not able to maintain production. A new Government holding company for steel, the Steel Authority of India Ltd. (SAIL), was established as part of an effort to reshape and revitalize the steel industry. SAIL will have jurisdiction over all phases of the steel industry and formulate long-term programs to involve industries such as coking coal, iron ore, and others necessary for steel production. India's steel industry has not been able to fully utilize existing plant capacity and, with high foreign exchange costs of imported steel, a critical supply shortage has persisted.

Capacity of the Bhilai steel plant was to increase from 2.75 to 4.4 million tons, according to an agreement signed in Moscow in July by representatives of India and the Soviet Union. Date of implementation of the project was not specified.

An announcement was made by the Government in September that it would establish a public sector company for construction and operation of a 275,000-ton capacity steel plant at Salem, Tamil Nadu. The company, to be known as the Salem Steel Co., would have an authorized investment of $133.3 million. Similar separate companies were expected to be set up for steel plants at Visakhapatnam and Vijayanagar.

Licenses for electric furnace-continuous casting steel plants, having a total capacity of 1 million tons per year, have been issued by the Government since the minimill program became a high-priority item. The plants would be located in 10 states.

Japan.—Recovery from the general world steel recession of 1971 was evident in Japan during 1972, as raw steel production reached a record high of 106.8 million tons. This was 4 million tons above the previous high annual production of 1970, and 9% over the 1971. The Japan Iron and Steel Federation listed the country's total raw steel capacity at approximately 137 million tons, and pig iron capacity at 105 million tons. The Ministry of International Trade and Industry (MITI) estimated raw steel capacity to reach 159 million tons in 1975. All pig iron capacity was by blast furnaces except 500,000 tons that represented output of electric and other furnaces. The 67 blast furnaces have an average daily capacity of 4,198 tons.

Of the 1972 total, steel produced by the basic oxygen process comprised 79.4%; by electric furnaces, 18.6%; and open hearths, 2.0%. In December, the Fukuyama Works of Nippon Kokan K. K. poured 111,660 tons of raw steel, which was reported as a record for one plant. The plant's No. 4 blast furnace had an average daily output of 11,150 tons for the month.

Nippon Steel Corp.'s eighth integrated steel plant, the Oita Works, started production in 1972. The plant started up two 300-ton basic oxygen converters with an annual capacity of 3.85 million tons which would supply continuous slab casters. Approximately 25% of Japan's raw steel production is made by continuously cast methods.

Pollution control was becoming a major concern of the Japanese iron and steel industry. In Japanese fiscal year 1972 approximately $265 million was scheduled for investment by the industry for control equipment. Of this, 63% would be for air pollution control, 23% for water pollution control, and the remainder for noise, industrial waste, and other controls. One company planned for a long-range offshore construction program to lessen contamination of populated areas by its steelworks.

Capital improvements were continued by all major producers, although at a reduced pace. Some blast furnace construction postponed because of the 1971 decline was started again and at least two large furnaces were placed in operation: Nippon Steel's Oita No. 1, which was in the 11,000-ton class, and its Tobata No. 4, initially scheduled at 8,800 tons per day, and to be expanded later to 11,000 tons.

Cartels approved by the Fair Trade Commission for eight major steel producers and six stainless steel companies were extended through December. The extension was made in June because of the supply-demand gap in various steels and the fear that the operators would suffer if the cartels were dissolved.

One result of Japan's large buildup of foreign exchange reserves has been to expand steel project financing and construction in other world areas. In 1972 Japanese assistance in construction of a second blast furnace and expansion of the Pohang steelworks in South Korea was planned. Japanese interests purchased land at Auburn, N.Y., and prepared to erect a steel mini-mill, which would be completed in 1974. Nippon Steel Corp., Mitsubishi Corp., and Mitsui & Co. signed agreements to invest in the Mexican steel firm Cía. Fundidora de Fierro y Acero de Monterrey S.A. (Fundidora), which was to expand production. Contracts were signed also by Nippon Steel for construction of two large blast furnaces in Brazil to be completed in 1974–75.

The technological, social, economic, and other factors affecting the Japanese steel industry were discussed by the executive director of Japan's Iron and Steel Institute.[4]

Korea, Republic of.—South Korea had underway an industrial expansion program oriented mainly around development of iron and steelmaking facilities. Under plans outlined by the Ministry of Commerce and Industry, shipbuilding would become the leading export industry, with an expected volume of $2 billion in 1980, compared with $15 million in 1972.

The country's first stainless steelworks began operation and reached designed capacity during the year. This operation, Samyang Special Steel at Ulsan, was in the first Asian country to produce stainless sheet, outside of Japan, using the Sendzimir mill. To help the new industry, the Government placed a ban on imports of sheet products similar to those produced by the plant. The Nation also had under construction its first integrated steelworks, the nationalized Pohang Iron and Steel Co. (POSCO). Capacity would exceed 1 million tons of steel annually in 1973, when the first blast furnace was to start up. Planned expansion called for a steel capacity of 2.9 million tons with a tentative completion date of 1978. The final goal would be 5.5 million tons of raw steel, and the operation has been planned accordingly for the future.

Luxembourg.—The two steel companies operating in Luxembourg accounted for approximately one-half of the Nation's industrial production and payroll, and 70% of its industrial exports. Aciéries Réunies de Burbach-Eich-Dudelange S.A. (ARBED) accounted for about 90% of the steel production and S.A. Minière et Métallurgique de Rodange (MMR) the remainder. ARBED completed a 5-year $250 million modernization program in 1972 designed mainly to increase productivity. Included in this program was replacement of small blast furnaces with larger and more efficient units, and the production of specific mill products at certain locations in order to minimize duplication. MMR was scheduled for improvements after a proposed merger. Luxembourg had a per capita steel production of 16 tons per person, the highest in the world. However, it exports approximately 95% of its output.

---

[4] Tabata, S. Problems and Actual Situation of the Japanese Iron and Steel Industry. Iron and Steel, v. 45, No. 3, June 1972, pp. 299–302.

Mexico.—Mexico's largest industrial venture, the Las Truchas steel complex, moved toward the construction stage with the completion of major planning details during 1972. The British Steel Corp. in competitive bidding, was awarded the position of project advisor. Suppliers for mill and ancillary equipment, estimated to have a value of $300 million, were registered and bids on the major items were expected to be awarded in 1973. The operating firm will be known as Siderúrgica Lázaro Cardenas-Las Truchas, S.A. (SICARTSA) and will have as its major stockholder the Government of Mexico. Overall cost of the first phase of the operation would be $500 million, with physical construction to begin the second half of 1973 and be completed in 1976. Production capacity for finished and semifinished steel would be approximately 1.4 million tons per year. A planned second stage, to increase capacity to 3.3 million tons per year, and costing $380 million, would be ready in the early 1980's.

The plant will be located at Las Truchas in the State of Michoacán. The port for the complex will be Lázaro Cárdenas, at the mouth of the Balas River on the Pacific Ocean. Dredging will be done under direction of the Navy Ministry and the dredged material used as fill at the plant site. Contamination of air and water is not expected to be a factor, since between 5% and 10% of total investment is to go for pollution control equipment.

The State-controlled Altos Hornos de México, S.A. was to add a second basic oxygen furnace and several arc furnaces in its short-term expansion program and reach a 4.4 million-ton capacity rate by 1975.

Fundidora planned basic oxygen furnace increases to obtain a 1.5-million-ton capacity figure by 1975. Japanese interest in the Mexican steel industry increased with purchase of 12% to 15% of Fundidora. Commitment by another Japanese group involving a new Mexican stainless steel plant was being considered.

A third sponge iron plant at Monterrey, was scheduled by Fierro Esponja. To be constructed by Swindell-Dressler Co. of the United States at a cost of $500 million, it would have an output of 1 million tons per year.

Netherlands.—The Dutch-West German steel combination, ESTEL N.V. (Hoesch-Hoogovens), announced plans to increase steelmaking capacity at IJmuiden by approximately 660,000 tons per year, or 10% above the 6.6 million-ton-per-year capacity of 1972. This expansion was expected to be sufficient to 1975–76, and would be used principally to supply the rolling mills at Dortmund, West Germany. A seventh blast furnace was started up at the IJmuiden complex during the year with a capacity of approximately 2.8 million tons per year.

The Dutch national steelworks Koninklijke Nederlandsche Hoogovens en Staalfrabrieken N.V., with facilities at IJmuiden concluded an agreement with Hoesch A.G. to form a common company on a financial level. Previously the two had attempted to obtain permission to construct a large, integrated steelplant on the reclaimed Maasvlakte area in Europort near Rotterdam. The plan was rejected by the city council under public pressure based on pollution problems.

South Africa, Republic of.—Construction of the steel mill complex at Newcastle by the Government-controlled South African Iron and Steel Industrial Corp. Ltd. (ISCOR) was well underway. Anticipated commissioning dates given for the new plant included 1974 for one coke oven battery of 2,500 tons per day and 1975 for a second. A 4,000-ton-per-day blast furnace would be commissioned in 1976. Total expenditures of about $1.5 billion have been planned for the complex, which would eventually employ 12,000 workers.

Expansion at the company's Pretoria works included a new oxygen steelmaking plant planned to be ready in 1976. At the Vanderbijlpark works, major projects scheduled for completion by 1976 included additional rolling mill capacity as well as blast furnace and melting plant capacity.

Spain.—Spanish steelmills recovered rapidly from the 1971 slowdown and ended the year with a 23% increase in raw steel production.

A concession was awarded to construct and operate the fourth integrated steelworks at Sagunto. The company approved for the project, Altos Hornos del Mediterraneo, was formed by Altos Hornos de Vizcaya S.A. and U.S. Steel Corp., the latter holding a 25-percent interest. Construction would be in three phases, extending through 1982 with capacity reaching 6 million tons of raw steel per year at that time. Included in the concession were several Government benefits, including essentially a total tax exemption for a period of 10 years. Investment for all phases was expected to reach $1.2 billion.

Continued expansion in the iron and steel sector is expected along with the country's industrial expansion. Apparent steel consumption was less than production for the first time in 1971, and exports of steel products are expected to become increasingly important in the future plans of this country.

Sweden.—The Government-owned steelworks, Norrbottens Järnverk AB (NJA) in Luleå, received approval to construct a coking plant at an estimated cost of approximately $71 million. This would supply coke for the expanding iron and steel operations at Luleå and provide an additional 200 jobs expected as a result of the project.

A contract for construction of a new blast furnace for Surahammars Bruks AB at its Surahammar plant was awarded to a British company. The company, a member of the Davy-Ashmore Group, would also furnish an oxygen converter. These units were scheduled for completion in 1974.

Sweden's iron and steel export trade amounts to about $1 billion. Special steel products are particularly significant, and Sweden has about 10% of the world market. Technological research in the fields of production, metallurgical processes, and equipment are heavily funded to maintain competitive advantage. Planned investments in the iron and steelworks sector for 1972 were estimated at approximately $39 million for plants and $143 million for equipment.

United Kingdom.—Implementation of the Government's plan for the British Steel Corp. (BSC) continued to be the major news in the iron and steel industry. The 10-year, $7.5-billion program to modernize the British steel industry was well underway, and some additional details were released. A loss of 50,000 jobs was expected as obsolete processing methods and plants were phased out. However, the strategic placing of factories to counter this job loss is an example of the planning which extends beyond consolidation of steel plants. Exact closure plans for the various steel plants would depend on market conditions and the country's future needs. With the United Kingdom joining the European Coal and Steel Community (ECSC), the official viewpoint was that BSC would have excellent growth prospects in a tariff-free market of 300 million people opening up over the next 4 years.

All of BSC's open-hearth furnaces would be closed by the end of the first 5 years of the plan, replaced by oxygen and electric-furnace steelmaking. Major construction was being done at the five integrated steelworks—Port Talbot, Llanwern, Lackenby, Scunthorpe, and Ravenscraig—and a new complex was being built at Teesside. All blast furnace pig iron production in the United Kingdom is controlled by BSC, as well as approximately 90% of its raw steel.

In the private sector new construction was in progress also. Programs included a new electric melting shop with vacuum refining furnaces; an electroslag remelting plant for Firth Brown Ltd.; and an argon-oxygen refining unit with a new ultra-power electric-arc furnace for Brown Bayley Steels Ltd., both at Sheffield. The fate of 27 open hearths remaining in the private sector was uncertain, but they could be expected to close out as BSC closes its 94 units.

A listing of the principal overseas investments of BSC International Ltd., a susidiary of BSC, was given.[5] The list included operations in Argentina, Canada, India, New Zealand, Republic of South Africa, and other countries.

Steelmaking, covering the next decade in northeast England was discussed in a two-part article.[6]

Mini-mill planning in the United Kingdom was active with one opened in 1972 and four scheduled or being planned for operation in the next few years.[7]

---

[5] Metal Bulletin. BSC International. No. 5744. Oct. 24, 1972, p. 30.

[6] Iron and Steel. Steelmaking in North-East England. V. 45, No. 1, February 1972, pp. 59–60 and pp. 61–71.

U.S.S.R.—Production of raw steel continued to increase at the 4% to 5% growth rate of the past few years, and additional capacity was underway in accordance with the current Soviet 5-year plan (1971–75). This plan placed production at 161 million tons in 1975, the target year.

New additions completed or underway at iron and steelmaking plants included a large blast furnace using natural gas injection, and basic oxygen converter facilities for the Novo-Lipetsk Iron and Steel Works at Lipetsk. Another blast furnace underway for the Krivoy Rog works in the Ukraine will have a volume of 177,000 cubic feet. Additional basic oxygen facilities were due to start up in 1973 at the Western Siberian Steel Works near Novokuznetsk.

Two developments expected to be of increasing importance to the steel industry are the tremendous natural gas reserves being developed and the increase in trade with the western world. The gas reserves are such that agreements have been signed with a number of European countries for 20-year periods. Future sales also may be made to Japan and the United States. Swedish studies made in 1972 included the feasibility of obtaining Soviet natural gas via a pipeline across the Baltic from Finland. Possible availability of Soviet gas would increase chances for direct reduction of iron at a number of locations. Present U.S.S.R. gas production used includes approximately 14% for iron and steelworks. Plans to construct a large steelworks at Kostamuska near the Finnish border has been announced with capacity as much as 5 million tons per year. Natural gas would be used for fuel and reductant in direct reduction units.

A contract for a turnkey steel materials plant was concluded with a combine of two American and three British companies. The plant will have five production lines and go on stream in 1975. Additional contracts were made for other specialized steelmaking equipment to be supplied by American and British firms.

Reportedly, sales of specialized Soviet-made steel mills were made to U.S. steelmakers. These were concluded following U.S. Patent Office approval of the Soviet inventors' applications for U.S. patent coverage.

TECHNOLOGY

Blast Furnace.—The trend toward large capacity blast furnaces appeared well established following continued successful Japanese operation of the 10,000-ton-per-day type in several plants. Japan started up two of this type in 1972, one rated at 11,000 tons per day, and another was expected to be operational in 1973. The U.S.S.R. was constructing two units designed for natural gas injection, which would average about 12,000-ton-per-day capacity.

Other countries having somewhat smaller designs included West Germany the Netherlands, France, and the United States. On completion, U.S. Steel Corp.'s 10,000-ton-per-day blast furnace at Gary, Ind. will replace five of the plants' older existing blast furnaces.[8]

Blast furnaces installed, under construction, or planned in the world increased by 28 during 1972. Japan had five new installations, the U.S.S.R. three, and one each in the United Kingdom, West Germany, and the United States. The average capacity of the units in Japan was approximately 4 million tons per year, and worldwide 2.89 million tons per year per blast furnace.

The Kaldo furnace appeared to be on the way out in the United States as Sharon Steel Corp. scheduled replacement of its installation at the Farrell works with top-blown basic oxygen converters.

A two-part review of the thermodynamics and kinetics of basic oxygen steelmaking and application of theoretical knowledge was published.[9]

Basic Oxygen Process (BOP).—The BOP's share of domestic steel production increased further in 1972 to 56%, from 53% in 1971. Capacity of the process was estimated at 82 million tons, and total world capacity at 370 million tons per year. Japan produced 79% or 84.9 million tons of its total 106.8 million tons of raw steel by the basic oxygen method in 1972.

[7] Metal Bulletin. UK Mini Mill Projects. No. 5764, Jan. 5, 1973, p. 28.

[8] Iron and Steel Engineer. Annual Review—Developments in the Iron and Steel Industry During 1972. V. 50, No. 1, January 1973, p. D31.

[9] Walker, R. D. and D. Anderson. Reaction Mechanisms in Basic Oxygen Steelmaking. Part 1. Iron and Steel, v. 45, No. 3, June 1972, pp. 271–276; Part 2 , v. 45, No. 4, August 1972, pp. 403–407.

The U.S. Steel Corp. had under construction at its Gary, Ind., and Fairfield, Ala., works bottom-blown oxygen converters. This modification of the oxygen process, known as Q-BOP, or QBM in Europe, has been licensed by the West German developer Maxhütte, and is in use in several European steelplants. One South African plant, ISCOR's Pretoria works, also has a commercial installation. Scheduled future investments indicated possible acceptance and gradual growth of the process. The principal innovation involves a double concentric tuyere arranged to allow central injection of pure oxygen shielded by an injected fluid hydrocarbon, either gaseous or liquid. Wear on refractory parts are reduced, pneumatic mixing accomplished, and greater oxygen efficiency achieved.

An innovation to the bottom-blown oxygen process for use in open-hearth furnaces was announced by Canada's Sydney Steel Corp. The process designated as the submerged injection process (SIP) uses the same tuyere construction employed by the Q-BOP or QBM process. International development would be handled by Maxhütte and technical developments in North America by Pennsylvania Engineering Co.

Electric Furnaces.—Production of raw steel in the United States by the electric arc furnace method increased over the previous year by 0.4% to 17.8% of the total. Although the percentage gain appeared low, an additional 30 furnaces were scheduled for completion by the iron and steel industry by 1974. Total electric furnace capacity was estimated at 32 million tons in 1972.

CF&I Steel Corp. had a new melt shop under construction at a cost of $13.5 million. This would have a 150-ton electric furnace and be ready in 1973. Lukens Steel Co. also had new electric melting facilities started, which included a 150-ton electric furnace, at a total cost of $18.8 million. The facilities would incorporate charging techniques to allow use of prereduced iron pellets and lessen dependence on scrap. The Ford Motor Co., Steel Division, had an electric furnace shop under construction which would contain two 200-ton electric arc furnaces. Smaller furnaces were being installed for a number of other steel and foundry companies.

The use of electric furnaces for small steelworks or mini-mills continued to increase in most areas of the world. In France three groups were formed to build mini-mills in that country, with a fourth project under consideration. Privately funded mini-mills announced for the United Kingdom will average at least one per year for the next 4 years. This expansion could eliminate what has been an annual scrap surplus in the United Kingdom. The BSC has started a study of the place of mini-mills in British steelmaking and, in a recent article, one of the United Kingdom's leading authorities indicated that 25% of that country's steel products might possibly be made on a mini-mill scale.[10]

The performance measurement of electric arc furnaces in steelmaking was discussed in an article,[11] and a method referred to for specifying conditions for lowest cost operation. One conclusion was that although practicable to operate a 400-ton arc furnace in the United States, it would not be recommended for the United Kingdom.

Future prospects for the arc furnace in steelmaking was outlined in a paper which was reviewed at the International Electroheat Congress in Warsaw.[12] Some results of continuously charging prereduced pellets to an electric furnace were given. Power consumption for test pellets 93.6% metallized and containing 92.2% total iron was given on a comparative basis as 585 kw-hr per metric ton and 500 kw-hr per metric ton for an all-scrap charge.

The techniques involved in determining the best process to be used for steelmaking, that is, the electric furnace versus the basic oxygen converter, as well as equipment selection for a particular situation, were discussed in an article.[13]

Iron and Steel Refining.—Additional argon-oxygen deoxidation (AOD) refining facilities were started up in the United States and the United Kingdom, and units were under construction in other countries. Fried. Krupp Hüttenwerke A. G. was licensed to use the Union Carbide process and will have the first installation in West Germany.

---

[10] Cartwright, Fred. Challenge of the Mini-Mills. Iron and Steel Review (India), v. 16, No. 6, November 1972, pp. 17–21.

[11] Davies, D. R. G., and A. H. Leckie. Performance Measurement—The DAP Concept. Journal of the Iron and Steel Institute, v. 210, Part 11, November 1972, pp. 817–825.

[12] Harrison, W. L., Electro-heat for the Iron and Steel Industries. Iron and Steel, v. 46, No. 1, February 1973, pp. 65–68.

[13] Kuhl, R. J. Selecting Processes and Equipment. J. Metals, v. 24, No. 6, June 1972, pp. 40–45.

In Sweden, Uddeholms AB reported on a modification involving the use of superheated steam to replace argon in the AOD process. A commercial installation was expected to be ready for operation in 1973 and reportedly would cut $8 per ton from the cost of producing stainless steel ingot.[14] Uddeholms will use bottom blowing in operation of the first converter at its Degerfors, Sweden, plant.

Electroslag remelting and refining (ESR) continued to attract attention, and a furnace installed at Sweden's Avesta Jernverks AB plant was capable of producing 10-ton stainless steel ingots. The increased interest in this process was tied to a trend toward increasing demand for superclean grades of stainless steel. Increased strength of the ESR steels were given as a big factor to consider along with lower production costs in comparison with other vacuum refining methods.

Lukens Steel Co.'s new ESR facility was discussed in an article from a standpoint of product qualities obtained by use of the method.[15] Slabs up to 30 tons and measuring 30 inches by 80 inches were produced in 1972.

Allegheny Ludlum Steel Corp. reported on two new stainless steel refining methods at the annual AISI meeting. Both were developed by the company. The first involved melting in a hot-blast cupola and transferring the hot metal to a BOP converter. Temperature in the bath rises to above 3,450° F at the end of an oxidation period resulting in low-carbon metal and minimum chromium losses. A second process, the Allegheny vacuum refining (AVR) process was reportedly used to decarburize charges of stainless steels previously melted in arc furnaces. Oxygen is injected below the surface of the metal while it is held under reduced pressure. Improved chromium yield over conventional air-melt practice is obtained.[16]

General reviews covering methods of vacuum treatment of steel during recent years, and some of the technical innovations involved were discussed in two articles.[17]

Direct Reduction.—Detailed coverage was given the state of the art at a seminar on direct reduction of iron ore held in Bucharest, Romania, September 18–23. The seminar, sponsored by the Economic Commission for Europe (ECE) covered developments of processes, and discussed to some extent their economic aspects. There were 142 speakers in the discussions and participants from 33 countries.

Total operating world capacity for prereduction was given as 2.86 million tons including partial prereduction. Capacity of plants under construction or expected to operate by 1974 would add an additional 3 million tons. This included U.S. Steel Corp.'s direct reduction plant in Venezuela, and Armco Steel Corp.'s plant near Houston, Tex. Both of these plants were in the process of eliminating startup problems prior to full-scale operation.

The first integrated steelworks in Western Europe using direct reduction was opened officially in April. This complex, Hamburger Stahlwerke, G.m.b.H., was reported to have an investment cost of approximately $120 per ton of annual capacity.[18] A description of major units of the plant were given.

The direct reduction plant constructed in Canada by Falconbridge Nickel Mines Ltd. to produce iron-nickel pellets closed in 1972. The plant first operated in 1971 and reached a maximum production rate of two-thirds of the annual design capacity prior to being shut down because of economic reasons.

A direct reduction plant for Western Australia was being studied by the Minister of Mines who discussed proposals with ATH officials in West Germany and visited the firm's Purofer plant.

An evaluation of prereduced materials

and trends for future steelmaking use were presented in an article along with brief discussions on some electric arc furnace tests. Trials using both pelletized and briquetted prereduced material were successful, with briquetts having a metallization in the 90% to 92% range giving excellent results.[19]

Continuous Casting.—Japan led the world in percent of raw steel production continuously cast with approximately 25% produced by this method. There were 63 casting machines with 146 strands operating in Japan. The U.S.S.R. led in number of units with 73 machines and 173 strands.[20] The United States operated 58 machines with 152 strands and continuously cast an estimated 5% to 6% of its raw steel production.

The largest continuous casting mill in Japan was at the Kashina works of Sumitomo Metal Industries, Ltd., where annual production of two strands was given at 1.3 million tons. In the United States, McLouth Steel Corp. was handling its entire output of steel with four single-strand casters. The capacity of the system was rated at 2.4 million tons per year. No ingots were being cast. The Gary works of U.S. Steel Corp. cast 22,391 tons of steel in its continuous-caster during an 83-hour period with no interruptions to set a record. Several grades of steel and 27 different cross-sectional sizes were cast during this period. Yield of prime slabs was reported as 98.6%.

Eastern Stainless Steel Co., as part of a modernization program, planned to continuously cast its output of stainless steel. A $7.6 million system will be in operation by 1974. Concast Inc. and Wean United Inc. agreed to cooperate in the development of continuous casting machines. Wean was to manufacture equipment under patents held by Concast.

In the United Kingdom, development of a horizontal continuous caster had reached pilot plant stage with good results reported. Saving over conventional methods was said to be significant. The U.S.S.R. was reported to have a large-scale horizontal unit operating.

Continuous casting units continued to be planned for and installed in a large number of countries throughout the world. These included Mexico, Canada, France, Italy, Sweden, India, Republic of South Africa, and Malaysia.

Powder Metallurgy.—Iron and steel powder producers were looking for substantial growth in the future, as technology of powder metal (PM) parts-forming processes improved. An official of Hoeganaes Corp., 80% owned by Interlake, Inc. and a leading producer, forecast iron powder shipments in 1980 at 310,000 tons.[21] This forecast was based on the assumption that hot forming of PM parts would reach large-volume proportions. The company indicated that continuing research and development would be carried out in the development of processing parameters as well as improved powders.

The potential of dense parts, mass produced from iron or iron-base powders, appeared good. High-density PM gears, containing 2% nickel, after sintering, heat treating, and tempering, attained yield strengths to 110,000 psi. Relating to concerns of the Occupational Safety and Health Administration, low-density iron powder for metallic brake linings was proposed to replace asbestos, a material which is cited as presenting industrial health problems.

General Motors Corp. Research Laboratories reported inexpensive powder produced from plant-generated machining and lathe turnings. Designated as Macromesh, the material was being considered as starting material for preforms; although coarser than conventional iron powders, the machining characteristics of the original stock are maintained.

A Ford Motor Co. official, in a speech to Forging Industry Association members at a Montreal meeting, reported that tests on various auto components from powdered metal looked good and cited the entire gear train as a potential use. The high cost of powdered metal was said to be a factor in holding the use down.

The production of high-speed tool steel from powder by a new economical process was announced by a company which made use of water atomization instead of gas, followed by an inexpensive process of converting the powder into billets. The lower cost advantage, plus uniformity and improved cutting qualities permitted, was expected to result in PM tool steel products competitive with those from conventional processing.

[19] Jensen, Harold B. Current Status of the Use and Production of Prereduced Iron. Iron and Steel Engineer, v. 49, No. 11, November 1972, pp. 59–66.

[20] Journal of Metals. USSR and Japan—1–2 in Casting. V. 24, No. 12, December 1972, p. 4.

[21] Holmes, R. R. Powder Metallurgy Entering a New Era. Amer. Metal Market, v. 79, No. 75, Apr. 18, 1972, pp. 11, 15.

Latest technical advances in providing equipment to eventually make possible continuous automatic production from powder to the finished component was discussed at a design and research conference held in Birmingham, England.[22] A U.S.S.R. paper discussed the use of hydrodynamic production of powder preforms and reported that iron powder compacts produced with 10% to 15% higher tensile strength than those statically formed could be further raised to 30% by using explosives.

Production of iron-base powders by a Canadian plant with a capacity of 70,000 tons per year was discussed in a publication.[23] Properties of products obtainable under various conditions were described.

Foundry.—Foundry trends were toward modernization with fewer but larger installations. More electric furnace melting at the expense of the cupola was indicated for the future, although large cupolas incorporating advanced technology, including pollution controls, were being planned or installed in increasing numbers. One usually would replace a number of smaller and less efficient units.

American Cast Iron Pipe Co. (ACIPCO) brought on stream a 150-inch-diameter, waterwall cupola with a melting capacity of 105 tons per hour of gray iron or 85 tons per hour of steel mix for ductile iron. Electric holding furnaces and a process control computer were installed to allow maximum process variable control and more economical operation. Another feature was air pollution control equipment designed to remove 99% of the furnace's particulate emissions. Total cost of the new facility was $6 million, of which pollution control equipment accounted for $1 million.

Pollution control continued to be of particular concern to the foundry industry because of relatively high capital costs for bringing equipment into compliance with the Occupational Safety and Health Act (OSHA). In a survey by Foundry,[24] the industry report showed that only 22% of the respondents considered their operations to meet the standards, with 21% not knowing, and 57% reporting standards as not being met. Plants expecting to purchase equipment of some type in 1973 totaled 74%, with 32% to purchase pollution control devices.

Oxygen enrichment of cupolas, although not new, was being reexamined as a partial solution to rising coke prices as well as air pollution restrictions. A detailed study of nine operations was made available by Airco Industrial Gases comparing normal operations with operations using oxygen injection. An average reduction of 41 pounds of coke was reported in injections ranging from 625 to 1,320 cubic feet of oxygen per ton of iron produced.[25]

The 39th International Foundry Congress was held in Philadelphia, Pa., May 8–12, and papers were presented covering several areas of technical progress. One paper dealt with large steel castings for nuclear reactors and the tests required for these; another with techniques used in surface coating of cast iron with alloys during casting.

A European converter process for making ductile iron and using metallic magnesium for nodulizing was described.[26] The new process utilized a special vessel, and was reported to allow simultaneous magnesium treatment, desulfurization, and carburization. Cost savings were cited over other nodulizing processes.

In England, the use of a novel rotary furnace using fuel oil was proposed for melting gray iron. Comparison of fuel consumption figures with a cold-blast furnace using coke and with an induction furnace using electricity indicated possible advantages in fuel cost and pollution controls. A 1-ton furnace required a melt time of 1½ hours with a firing rate of 30 gallons of oil per hour to provide a ton of molten iron from cold metal.[27]

Research and Development.—Projects connected with iron and steelmaking were active at four Bureau of Mines Metallurgy Research Centers during the year. The production of steel from urban refuse, and the control of detrimental effects in steels containing tramp copper were two projects under study at the Albany Metallurgy Research Center. The Rolla Metallurgy Research Center was studying hot rolling and forging of ductile iron, and the production of recyclable iron products from mill scale and from steelmaking and iron foundry dust. At the Twin Cities Metallurgy Research Center, projects to determine minimum use of fluorspar in basic oxygen steelmaking and evaluations of possible substitutes were underway. Another project had as its objective the production of commercial grades of pig iron from low-grade ferrous scrap. The College Park Metallurgy Research Center operated a new, 5-ton-per-hour pilot plant to handle raw refuse, and along with other products, recover light iron, including tin cans, and heavy iron. Additional research was started to devise methods of utilizing the ferrous fractions as charge material for the electric-arc steelmaking furnace, and in producing a commercial-grade pig iron.

Other ferrous research projects included one at the University of Michigan on leaching of copper from steel scrap. The University of Pennsylvania's metallurgy department worked on the iron-copper-carbon system and results suggested a possible liquation process for separating copper and iron in copper-bearing steel scrap.[28] A review of use of rare earths in the high-strength low-alloy (HSLA) steels was published; the United States is a basic supplier of rare-earth raw materials to the rest of the world.[29]

Stainless steel producers reported continuing research and development studies of new types of steels for high-temperature and corrosion applications for an expanding stainless market. One new austenitic stainless steel produced by Armco was said to have corrosion resistance superior to type 316 steel, among other properties.[30]

Shaped tin-free steel beverage cans were in test production using a new patented process involving deep drawing of the steel. This process was expected to permit the economical substitution of steel cans for a large segment of the beverage market now serviced by aluminum. For coated steels, the powder coating method was moving from the laboratory into test production. Several manufacturers, including automotive manufacturers, had started field tests.[31] The substitution of dry plastic coatings for liquid coatings of metal was also being studied as a substitute for galvanized steel. Patents held by General Electric's Lamp Metals and Components Department were being used by a company formed for the purpose of die casting ferrous metals. Die cast tools were said to be lower in cost than those produced by powder metal tool methods.

The Ford Motor Co., to improve productivity and quality of the products, was instituting automated pouring equipment in its new iron foundry. Automatic pouring, a recently developed technique, is expected to be specified for all new high-volume casting plants in the future. The American Steel Foundries, subsidiary of Amsted Industries, planned to invest more than $300,000 in new facilities to test freight car components in the company's Illinois product development and test laboratory. This laboratory operates one of the largest railroad research programs in the country.[32]

The development of continuous steelmaking was kept alive by the operation of the IRSID plant at the Hagondange works of Wendel-Sidélor in France. The 25-ton-per-hour continuous steelmaking unit produced over 20,000 tons of steel of various grades since the start of operation in 1971.[33]

In the United Kingdom, BSC continued to reorganize its research laboratories. In addition to the corporate laboratories, responsible to the director of research and development, there were to be research departments in each product division. These would be organized as follows: (1) The strip mills division would concentrate all of its research work at the Port Talbot laboratories; (2) the general steel division would construct a new laboratory near Middlesborough; (3) the special steels division would reorganize work in the Swinden laboratories at Rotherham, and in addition, would serve as the physical metallurgy center for the corporation as a whole; (4) the tubes division would have its research organization centered at Corvey, and also maintain four branches. The corporate laboratories have been completely reorganized. They evolved largely from the former BISRA organization and now consist of three separate laboratories: (1) the advanced process laboratory at Teesside concerned with new methods of iron and steelmaking; (2) the corporate development laboratory at Sheffield engaged in new ventures which do not fall within the interests of a particular division; and (3) the corporate engineering laboratory at Battersea, London, which is involved mainly in development and design of improved steelworks plant and engineering systems. In addition, a number of centers have been created with special duties such as nondestructive testing. As part of BSC's large-scale development work, a blast furnace operation using formed coke ran for 5 days with 100% replacement of conventional coke without any noticeable change in operating characteristics. These results and former tests indicated that the formed coke, or briquetted material could be used on a 100% basis although the gross fuel requirement would be increased to some extent. Flue dust losses increased but created no problems in the gas cleaning system.

In Japan MITI announced plans to start a 6-year program for development of a nuclear-powered steel mill system to begin in 1973. Plans included development of a pilot system to produce reduced iron containing 95% or more Fe by utilizing the nuclear heat. The latter project would have a funding of $26 million. A new system to desulfurize pig iron was announced by Sumitomo Metal Industries. This system involved the use of a sloped rotary kiln in which the desulfurizing reagents were added and rotated for 2 to 4 minutes with the molten iron. Reduction of pig to less than 0.005% sulfur content was claimed.

The use of magnesium to desulfurize molten steel was entering the developmental stage in the United States, and was expected to be in general use as soon as injection problems were solved.

Another method of desulfurizing molten pig iron came from West Germany with the announcement of August Thyssen-Hütte A.G. of an experimental operation performed at its Beeckerwerth steelplant. This operation involved calcium carbide injected by lance into the molten pig iron on a molten metal car as it is moved from the blast furnace to the steel furnace.

In Sweden the Metallurgical Research Station in Luleå built a blast furnace simulator which permits the study of the molten metals in the range of 1,000° to 1,500° C., and allows the study of the different materials under controlled conditions.

Pollution Control.—In 1972 the domestic steel industry placed in operation pollution abatement equipment costing $202 million. Since 1965 the industry has invested $1.3 billion and has budgeted for the future $336 million for control equipment installations. Industry experts estimated that the cost per year to maintain the equipment would be approximately 12% of the original construction cost. Approximately 60% of the cost for control installations has been for air purification and the remainder for water quality control. Although all steel producers were moving to meet the standards set by the quality control act of 1970, the ability of the industry to provide the capital, meet operating costs of pollution control equipment, and continue to install necessary processing equipment without substantial price increases on products was questioned.[34] The resolution of the environmental problems facing the industry will be of primary concern to all steelmakers in the next few years, along with the problem of steel imports.

The iron and steel foundries were no less concerned over increased costs owing to environmental control requirements than the steelmakers. Many of the smaller foundries have been forced to cease operations because low-profit margins did not allow installation of necessary pollution control equipment. Where possible, cost increases will be passed on to consumers and the foundry will install the needed equipment. However, it was indicated that a substantial amount of smaller foundry production will be assumed by the larger foundries and a part imported as castings before the environmental standards compliance is resolved. The effect of environmental control on cost of domestic castings has been given at from more to $14 per ton for the smaller foundries to under $2 per ton for the larger ones.

---

[34] Industry Week. EPA, Steel Tiff Over Cleanup Costs May Be First of Many. Nov. 6, 1972, pp. 18–20, 58.

Iron foundry population was projected to continue to decline to about 1,000 in 1980, although production trends are for a continuing growth rate projected at 2% per year.[35] Domestic iron and steel foundries in 1972 numbered approximately 1,900.

One method that has been gaining the favor for the reduction of air pollution in plants producing ductile iron has been the use of new nodulizers, such as Remag, a magnesium-containing additive developed by the U.S. Pipe and Foundry Co. This type of product is reported to sharply reduce fume and visible flare during the addition operations.

A paper on air pollution control in the British iron and steel industry presented at the last International Pollution Control and Noise Abatement Conference held in Sweden, was reproduced for discussion.[36] Systems used for the various steelmaking processes were covered.

A new vacuum, two-stage steelmaking process developed in Sweden by SKF Stål was publicized as having a very low level of environmental pollution, as well as a higher utilization of electric power and equipment than conventional electric-arc methods.[37]

In Japan the outlay for pollution control planned by the six major steelmakers amounted to approximately $280 million for Japanese fiscal year 1973, compared with $265 million in Japanese fiscal year 1972. The investments by the six firms was about 15% of total investments for the plants. MITI was studying various measures to control air pollution and set the time table for sulfur dioxide emission standards compliance ahead by 1 year. A 0.015 parts per million standard also was adopted for SO_2.

Table 2.—Pig iron produced and shipped in the United States, in 1972, by State

(Thousand short tons and thousand dollars)

State	Production	Shipped from furnaces		Average value
		Quantity	Value	
Alabama	4,086	4,083	277,745	68.03

[e] Estimate. [p] Preliminary. [r] Revised.

[1] Table excludes all ferroalloy production except where otherwise noted.

[2] In addition to the countries listed, North Vietnam and Zaire presumably have facilities to produce pig iron, but available information is inadequate to make reliable estimates of output levels.

[3] Includes sponge iron output as follows in thousand short tons: Mexico: 1970—679; 1971—743; 1972—865; Sweden: 1970—204; 1971—192; 1972—196.

[4] Includes ferroalloys, if any are produced.

[5] Includes blast furnace ferroalloys.

[6] May include ferroalloys.

[7] Includes blast furnace ferroalloys except ferromanganese and speigeleisen.

[8] Revised to exclude blast furnace ferrosilicon.

[9] Includes blast furnace ferroalloys, if any are produced.

[10] Includes ferroalloy production.

[e] Estimate. [p] Preliminary. [r] Revised. NA Not available.

[1] Steel formed in first solid state after melting suitable for further processing or sale.

[2] Pakistan was reported as a steel producing country in previous editions of this chapter, but all known crude steel production was in the former East Wing of this country, which has now become the independent nation of Bangladesh; accordingly, all output formerly credited to Pakistan is now credited to Bangladesh. In addition to the countries listed, North Vietnam produces raw steel, but information is inadequate to make reliable estimates of output levels.

[3] Data from American Iron and Steel Institute (AISI). Excludes steel produced by foundries not reporting output to AISI but reported to Bureau of Census as follows (in thousand tons): 1970—1,723; 1971—1,583; 1972—1,610.

[4] Ingots only.

[5] Apparently excludes shipyards' production of steel castings.

Iron and Steel Scrap

By Harold J. Polta [1]

Although domestic consumption of iron and steel scrap in the first half of the year was below that in 1971, the continued high consumption rate thereafter brought total consumption in 1972 within 1 million tons of the record high established in 1969. Exports followed a similar pattern, with monthly exports generally below those in 1971 early in the year, but with increases the latter half sufficient to make 1972 exports more than a million tons above those in 1971. The increased demand for scrap reflected the increase in steel production as the steel industry recovered from the effects of inventory building (in anticipation of a strike in the steel industry in 1971) and improved worldwide business conditions. With increased demand, scrap prices reversed their downward trend of the past several years and moved generally upward.

Interest in iron and steel scrap continued high. Spurred by environmental organizations, an increasing number of States passed legislation designed to increase recycling of junked vehicles, and a bill to encourage use of scrap was introduced in the U.S. Congress. Steel companies, can manufacturers, and scrap processors cooperated with other interested groups to operate recycling centers for the collection and disposal of tin cans. Auto manufacturers were helping communities collect and dispose of junked vehicles. A growing number of communities were reclaiming scrap from municipal refuse, and more were planning construction of facilities for this purpose. Technical foundations, consulting groups, and universities had numerous studies underway on all phases of the iron and steel scrap problems. And because it considered an international scrap shortage a real possibility within only a year or two, the International Institute of Iron and Steel established a group of experts from around the world to assess the relationship of supply and demand of scrap on the international market during the 1973–1980 period.

The Bureau of Mines agreed with the stand of the Institute of Scrap Iron and Steel that increased recycling of scrap would come only with increased demand. However, it considered technology the only ultimate answer and therefore continued researching ways to improve scrap quality and increase uses for low-quality scrap.

Legislation and Government Programs.—H.R. 15770, "A Bill to amend the Internal Revenue Code of 1954 to provide reasonable and necessary income tax incentives to encourage the utilization of recycled solid waste materials and to offset existing income tax advantages which promote depletion of virgin natural resources," was introduced in the House of Representatives on June 29. However, while there was general unanimity on the objectives of the bill, there was considerable controversy about the specifics on how to best achieve these objectives even by the major associations of secondary metal processors. By yearend no bill with these or similar objectives had been enacted into law, but there were indications that similar legislation would receive consideration in 1973.

In January the Department of Commerce announced that exporters were no longer required to submit semimonthly reports on exports of iron and steel scrap and nickel-bearing scrap. The Department had started requiring weekly reporting in November 1970, and had amended this to semimonthly reporting in August 1971. However, near the end of the year consumers again requested export controls from the Department of Commerce because they feared the combination of increased steel production and bumper exports of scrap would cause a critical shortage of scrap. Representatives of the scrap processing industry disputed this and insisted that there was no scrap shortage. By yearend no action had been taken, but Commerce experts continued to study the situation.

Late in the year the Supreme Court agreed to review the responsibility of a Federal regulatory agency to make environmental impact assessments before approving transportation rate increases. This followed a controversy involving the railroads, scrap shippers, environmental groups, and the Interstate Commerce Commission (ICC). On October 4 the ICC entered a final order authorizing permanent rate increases, including increases on recyclable materials, which generally averaged 3%. But on November 8 the rate increases on recyclable materials was suspended until June 10, 1973, and further proceedings were opened on the environmental effects.

By October the Minnesota Pollution Control Agency (PCA) had ratified 23 contracts for the collection of an estimated 20,000 auto hulks in accordance with Minnesota's Abandoned Automobile Law, which was passed last year. The legislation provides for a $1 recycling fee on each transfer of title of a motor vehicle. Revenues collected are passed on to counties and municipalities for use in collecting abandoned and junked automobiles. Based on scrap processor prices, truckers then bid to the State for hauling the community-gathered hulks to the processor. Because the approach appeared to have the approval of all segments concerned with the junk auto problem, operation of the legislation was being watched with considerable interest.

In mid-July, Connecticut officials selected General Electric Corp. to develop and manage a Statewide system to dispose of solid wastes with maximum recovery of material and energy.[2] The recovery of 630,000 tons of ferrous and nonferrous metals could result from the plan. The State and the Federal Environmental Protection Agency provided $450,000 in contract funds for the year-long study; a project team from General Electric Corp. and the Southern Connecticut Gas Co. were to contribute an additional $665,000 in worktime.

The magnetic separation system scheduled for processing solid waste by Great Falls, Mont., starting in mid-1973 will make it the 33d community operating, or planning to operate, a magnetic reclamation system.[3] Communities included in the list were Amarillo, Tex., Atlanta, Ga., Chicago, Ill., Franklin, Ohio, Houston, Tex., Los Gatos, Calif., Madison, Wis., Martinez, Calif., Melrose Park, Ill., New Castle County, Del., Pompano Beach, Fla., St. Louis, Mo., St. Petersburg, Fla., Stickney, Ill., and Tampa, Fla.

In Wilmington, Del., a new $2 million reclamation facility, believed to be the largest in the world, was dedicated in midyear.[4] The plant, consisting principally of a trash shredder and magnetic separator, is hoped to obtain considerable revenue from the sale of reclaimed cans. However, there were doubts about whether the cans could be detinned and then used by the iron and steel industry economically.

[4] American Metal Market. Detinning May Decide Success of Recycling Plant. V. 79, No. 158, Aug. 30, 1972, p. 14.

The Tennessee Valley Authority (TVA) assisted valley counties in the collection of about 12,000 junked automobiles. TVA equipped seven trucks for loan to counties for junked autos. Cost of collecting was estimated to be between $6 and $8 per car. Plans were to expand the cooperative program.

In Virginia, 25 soldiers from Ft. Lee worked 6 weeks to collect about 500 of the estimated 2,000 junked vehicles in the Petersburg area. This followed a similar project in Goochland County. In both instances, police cooperated by providing escort and getting releases signed so that the vehicles could be moved.

Milwaukee was considering installation of a shredder system similar to the one in operation at Madison which recovers ferrous metals magnetically from shredded trash.

In South Dakota, Operation Pride was initiated by the Chicago and Northwestern Railway Co. to rid a 10-county area of its derelict cars through volunteer efforts.[5] Civic organizations located and made arrangements for pickup of the junked vehicles by trucks loaned by cooperating public and private organizations for delivery to collection scrap yards.

In California, the Los Angeles By-Product Co. was extracting cans magnetically from trash, cleaning and shredding the cans, and selling the shredded metal to the copper industry for use in recovering copper. The firm was processing garbage from Oakland, Piedmont, Emeryville, Albany, San Leandro, Sacramento, Walnut Creek, Concord, Lafayette, and several other Contra Costa County communities. Plans were to expand the program to other cities.[6]

The city of Palo Alto, Calif., was considering a shredding process for total recycling of garbage. The recycling center was operated at a loss of $32,000 in 1972, handling only a very small proportion of the city's total refuse, which included 75,000 vehicles.

In September the Environmental Protection Agency awarded resource recovery demonstration grants worth $20.3 million to four governmental units: Baltimore, Md., $6 million; San Diego County, Calif., $3 million; State of Delaware, $9 million; and Lowell, Mass., $2.4 million.

Processing material collected by ecology groups, municipalities, and can manufacturers, the Proler Steel Corp., Houston, Tex. sold about 200,000 tons of can scrap to the copper industry according to a spokesman for the company.[7] The firm processed the scrap for this market in its plants in El Paso, Tex., Copperton, Utah, and Chicago, Ill. The increase in the use of cans for precipitating copper in recent years, estimated at 600,000 tons in 1972, has encouraged environmentalists to view the copper industry as a major market for reclaimed cans. However, the two largest precipitated copper processors, Kennecott Copper Corp. and The Anaconda Company, see only a gradual expansion of the process over the next few years, according to spokesmen for the companies.

AVAILABLE SUPPLY

The new supply of iron and steel scrap available for consumption at consumer's plants in 1972 was 92.9 million short tons. It consisted of 51.2 million tons of home scrap, and 40.3 million tons of purchased scrap (net receipts). Compared with 1971 figures, home scrap production was up 4.1% and net receipts were up 18.6%.

CONSUMPTION

Consumers reported consumption of 93.4 million tons of iron and steel scrap in 1972. This was a 13% increase over consumption of the year before, and only 1.5% below the record high established in 1969. Consumption consisted of 51.2 million tons of home scrap (assuming reported scrap production equals consumption of home scrap), and 42.2 million tons of purchased scrap (assuming consumption of purchased scrap equals total scrap consumption minus scrap production).

[7] American Metal Market. Use of Steel Scrap to Produce Copper from Copper Ore Jumps. V. 79, No. 237, Dec. 27, 1972, pp. 14–15.

STOCKS

The stockpile of 8.2 million tons of iron and steel scrap reported on hand at consumers' plants on December 31, 1972, was 4% below that reported on hand the previous yearend. During the first half of the year the end-of-month stocks remained between 8.2 and 8.4 million tons; then they rose rapidly to a high of nearly 8.8 million tons in August. Thereafter they declined, so that by yearend they were 325,000 tons below those reported at the end of 1971.

PRICES

Prices of iron and steel scrap rose sharply at the beginning of 1972, then leveled off, but started to rise again in late July. Thereafter prices continued to rise so that by yearend the Iron Age No. 1 heavy melting price of $46.17 equaled the monthly average peak established in February 1970. The December average No. 1 heavy melting price of $43.16 was 44% above the December average in 1971. It was the highest monthly average price since 1960 with the exception of February and March 1970 when the monthly average for No. 1 heavy melting was $46.17 and $43.83, respectively.

FOREIGN TRADE

Exports of iron and steel scrap were below those in 1971 the first half of the year, but the continued high export rate thereafter made total exports for the year well above those of the year before. The 1972 total, 7.2 million short tons (excluding rerolling material, and ships, boats, and other vessels for scrapping), was 18% above that exported in 1971, but 29% below the record high exports of 1970. Japan again was the largest importer of U.S. scrap, taking 32% of total exports. Next largest importer of U.S. scrap was Canada, which took 13%. Spain and Italy each received 10% of U.S. scrap exports.

No. 1 heavy melting continued as the largest export grade, accounting for 32% of the total. Next largest export grades were shredded and No. 2 bundles, which accounted for 20% and 12%, respectively.

WORLD REVIEW

Exports of iron and steel scrap from the United Kingdom approached 772,000 short tons in the first half of 1972. This was made possible because of relaxation of restrictions on most grades of scrap in 1971 and because of decreased domestic demand resulting from the recession in the steel industry. With improvements in the British steel industry, domestic demand for scrap rose and export restrictions on the better grades of scrap were to be reimposed by the Department of Trade and Industry on September 11. However, the reimposition of controls was delayed until the end of October because of a prolonged dock strike.

At the same time, discussions were being held between the British Scrap Federation, the British Steel Corp. (BSC), and the British Independent Steel Producers Association concerning future arrangements with the scrap industry when the United Kingdom would become a member of the European Community (EC). Although the United Kingdom was scheduled to become part of the EC on January 1, 1973, it had secured agreement in its negotiations with the EC for a transitional period of up to 2 years during which restrictions on the British industry could remain. Since the 1930's BSC and the scrap merchants had operated under an agreement which guaranteed negotiated prices, provided for a scrap grading system, and gave preference to scrap arising in the United Kingdom. After the transitional period the United Kingdom would have to abide by EC rules. These rules would make export controls on scrap by the United Kingdom no longer permissible. After successful negotiation for the 2-year transition period in response to requests from the British steel industry, the industry at the turn of the year surprisingly announced that the long standing scrap merchant-steel industry agreement would be terminated in July 1973.

In addition to the concerns about how entry into the EC would affect the United Kingdom steel and scrap industries, the British shared the concern with other countries of possible scrap shortages in the years ahead. With one private sector mini steel mill already operating and several more being planned including, possibly, similar installations by BSC, the demand for scrap was expected to grow significantly. The virtual ban on overseas sales of scrap scheduled to begin February 1, 1973, and the start of negotiations for imports from the Soviet Union were signs of the growing concern about the ability of the British scrap merchants to supply the needs of the British steel industry.

According to an official in its Steel Division, the EC established an overall export

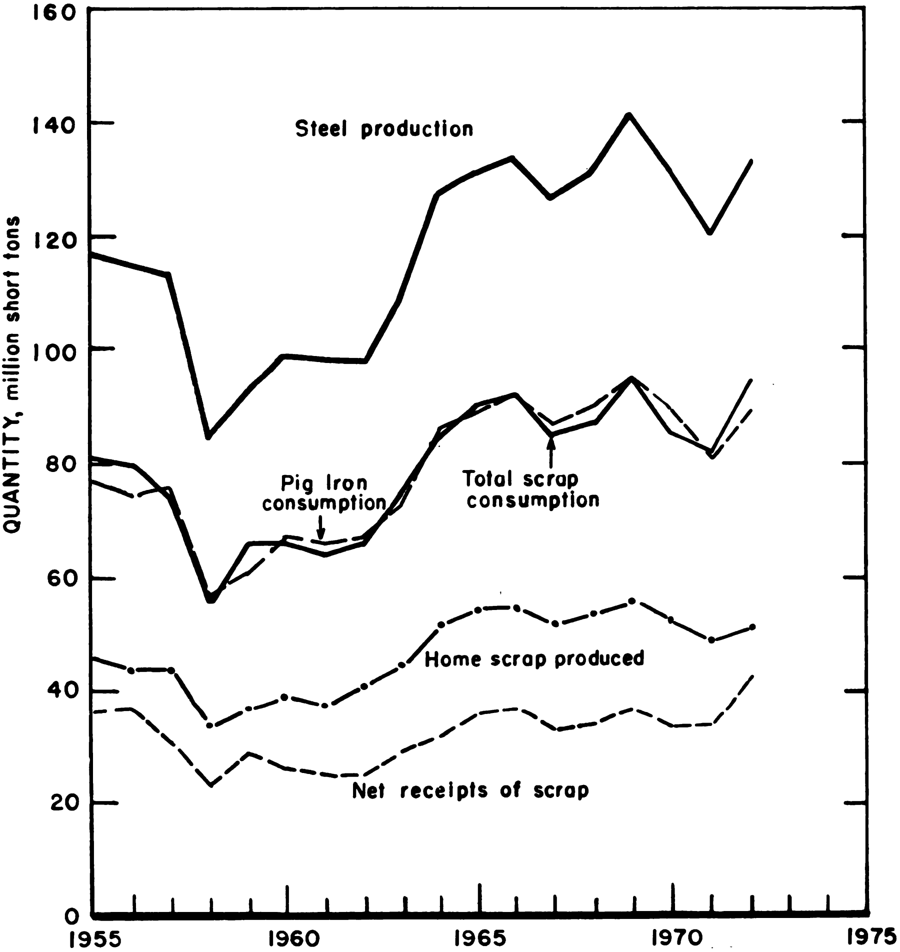

Figure 1.—Steel production (AISI); total iron and steel scrap consumption; pig iron consumption; home scrap production; and net scrap receipt.

ceiling of 178,000 tons for the first half of 1973. The decision guaranteed an export quota of 55,000 tons to West Germany, 80,000 tons to France, and 33,000 tons to the Netherlands. However, the decision could be reexamined at any time and had to be reexamined before March 31, 1973.

In France, regrouping of the ferrous scrap processing industry through mergers and takeovers left the country with only four major scrap processors.[8] The regroupment was reported to have given financing ability for branching out into such ventures as mini-steel mills, four of which were cited as being in the planning stage. Steady, but low demand for scrap throughout the year had the price of No. 1 scrap as low as $20 a ton. However, demand increased sharply in November so that the price rose to $30 by the end of the year. French scrap processors are subject to EC Commission rules and apparently are somewhat frustrated by export controls to third countries.

Luxembourg reported consumption of 1.6 million tons of iron and steel scrap in 1972. Most of this came from domestic sources. Imports, principally from its EC partners, supplied only 321,000 tons. Luxembourg does not export any scrap, and there are no special price controls in effect.

TECHNOLOGY

Processors of scrap continued to upgrade scrap, particularly through the use of shredders. The 100 or so shredders built in the past 10 years have an annual shredding capacity of about 4 million tons. The use of auto flatteners has greatly increased the number of junked autos that can be hauled on a vehicle and has extended the economic haul distance for junked autos considerably.

With most areas in the country, where huge generations of scrap exist, already having very large shredding plants capable of shredding 10,000 to 18,000 tons a month, the trend was towards the design and marketing of smaller less expensive shredding facilities. At the Third Mineral Waste Utilization Symposium in March,[9] a participant stated that the country could support an additional 100 shredding plants having a 3,000-to 4,000-ton-per-month capacity. According to calculations presented, capital investment of about $750,000 was required for such an installation. The "Auto Reduction Mill" designed and installed in St. Paul by Dravo Corp. was the first shredder type machine with hammers rotating about a vertical axis.[10] Chief advantage of the 30-ton-per-hour capacity mill, according to the corporation, was its ability to produce a denser product than the conventional hammermill-type shredder. In Wisconsin the Appleton Machine Co. was building a preshredder for the Ripsteel Corp.[11] The machine was designed to tear automobiles into small pieces that could be either baled or fed continuously into a small high-speed hammermill.

Early in the year National Steel Corp. demonstrated to an audience of public officials, food and beverage packers, can manufacturers, and conservationists that it is technically feasible to use scrap steel cans in steelmaking by including 8 tons of cans to an electric furnace heat and 37.5 tons of scrap to the charge of a blast furnace at the rate of 50 pounds per ton of hot metal produced.[12]

Following an American Iron and Steel Institute contract with Swindell-Dressler Corp. for evaluating various techniques for separating ferrous materials (including cans) from municipal wastes deposited at transfer stations prior to their incineration or burial in land fills, National Steel Corp. joined Stroh Brewery Co. in commissioning Swindell-Dressler to make a follow-up study, namely, the reclamation and remelting of incinerated scrap steel cans into new primary steel.

[12] American Metal Market. New Mill Capabilities Shown in Steel Can Recycling. V. 79, No. 12, Jan. 18, 1972, p. 17.

Full-scale tests at Bethlehem Steel Corp.'s Homer Research Laboratories demonstrated the technical feasibility of high-temperature scrap preheating according to an engineer of the corporation.[13] Economic advantages in each case, however, would have to be weighed against local conditions ranging from characteristics of available scrap, cost, and availability of electric power, and the need for additional productivity. According to the company, favorable scrap characteristics and a satisfactory bucket height-to-diameter ratio would make it possible to preheat scrap to an average temperature of 1,350°F, and thus to realize a 20% increase in productivity and a 20% lower power consumption.

Avco Systems Div. Avco Corp., of Lowell, Mass., was building a prototype model of a ferromagnetic fluid system for separating mixed nonferrous metals.[14] One of the major applications would be the processing of fragmentized auto scrap after the ferrous materials had been removed by magnetic separation.

Whirlpool Corp. was conducting a pilot test program to study various ways of processing wornout appliances for usable steel in a separation and compaction process.[15] The processed appliances were then shipped to Inland Steel Corp. for test melts to determine what steelmaking problems would be encountered.

General Motors Corp. reportedly was hoping to increase internal scrap consumption through several innovative processes.[16] With its "XtrueCast" process the corporation was hoping to convert sheet metal offal, turnings, bar ends, and forging flash into bar stock. With another technique it was using waste material, and turning it into "Macro Mesh," a coarse metal powder suitable for making metal parts such as pole shoes for automobile starter motors. This process involves vapor degreasing to remove cutting oil, separation of trash, shredding, and screening.

The Bureau of Mines continued to direct considerable attention to finding ways to improve scrap quality and/or ways to use lower quality scrap. At its metallurgy research center in College Park, Md., the Bureau was studying ways to improve and optimize its pilot plant for processing municipal incinerator residue. Much of the crude incinerator residue fed to the plant was from municipalities that were under consideration for funding of demonstration plants of similar design by the Environmental Protection Agency. The iron and steel, copper, and other scrap concentrate fractions from the plant were made available to Bureau and industry metallurgists for other research projects. At College Park these included producing and evaluating products made from melts of incinerated can scrap, and removing copper from molten ferrous scrap. Plans were to also study raw municipal refuse and a laboratory scale plant was being assembled for this purpose. Objectives were to gather data on composition, particularly percentages of individual metals and alloys; separate scrap metals and other potentially valuable components from the refuse; make cost analyses of the process; and provide concentrate samples for utilization research.

At the Bureau's Twin Cities Research Center in Minnesota, metallurgists were investigating the effects of impurities in incinerator residue scrap on the properties of synthetic foundry pig and gray iron. Plans were to similarly investigate effects of impurities on metal products made from shredded automobile scrap and machine-shop chips and turnings. Other research hoped to develop a process to remove copper from aggregates of copper, glass, iron, and organic resins or fibers using an electrochemical salt cell. Another project had as its objective the removal of nonferrous contaminants from iron oxide products through use of a pelletization-chlorinization process. The hypothesis that removing seats from cars before shredding reduces copper content was also being investigated.

Metallurgists at the Bureau's Albany, Oreg. Research Center were developing electric steelmaking practices for utilizing the ferrous fraction of urban waste in the production of carbon and low-alloy steels. They were investigating the nature of the scrap recovered from urban waste, how the material relates to scrap specifications used by steelmakers, and procedures that could lead to efficient use of processed scrap.

---

[16] Industry Week. GM turning scrap into metal powder. V. 173, No. 2, Apr. 10, 1972, p. 24.

At Salt Lake City, Utah, Bureau researchers were concluding studies on the processing of shredded municipal refuse through horizontal and vertical air classification, and were gathering data to make a cost analysis of the process. They were also continuing studies directed towards increasing recycling of obsolete automobiles, and other vehicles. These included studying the economics of incinerating auto hulks prior to shredding; testing the nonferrous metal concentrate to determine the most efficient and economic method to separate aluminum, copper, and zinc die castings; and developing continuous cryogenic systems for reclaiming copper from insulated wires, crushing tires, and recovering iron and copper from small motors and generators.

At Rolla, Mo., Bureau metallurgists were investigating the effects of copper and tin, singly and in combination, and other impurities on properties of ductile iron castings. This research supplemented, and was coordinated with, past and ongoing Bureau sponsored research at the University of Wisconsin. Because copper and tin are so difficult to remove when alloyed with iron and steel, these studies were investigating and trying to determine precisely how copper and tin affect the properties of ferrous metals containing these elements.

A complete list of Bureau of Mines scrap-related research efforts is contained in an information circular on the subject.[17]

---

U.S. total [1]	11,541	5,970	17,292	253	860
Pig iron	3,010	--	2,873	147	277
TOTAL—ALL TYPES OF MANUFACTURERS					
Carbon steel:					
Low-phosphorous plate and punchings	2,060	220	2,271	18	168
Cut structural and plate	1,660	95	1,740	7	120
No. 1 heavy melting steel	9,456	20,450	28,331	1,941	2,631
No. 2 heavy melting steel	2,336	1,112	3,422	94	331
No. 1 and electric furnace bundles	6,599	731	7,221	87	884
No. 2 and all other bundles	3,260	534	3,683	127	394
Turnings and borings	2,244	385	2,440	204	241
Slag scrap (Fe content)	1,414	1,780	3,099	119	87
Shredded or fragmentized	2,064	--	2,062	2	100
All other carbon steel scrap	6,315	13,024	17,959	1,217	1,357
Stainless steel	438	589	969	52	109
Alloy steel (except stainless)	608	2,112	2,728	82	280
Cast iron (includes borings)	7,010	9,379	15,074	1,433	1,412
Other grades of scrap	1,657	773	2,372	67	55
U.S. total [1]	47,120	51,184	93,371	5,450	8,169
Pig iron [2]	7,205	88,941	89,140	6,863	1,660

[1] Data may not add to totals shown because of independent rounding.
[2] Includes all pig iron used in reporting establishments.

Table 3.—Consumption of iron and steel scrap and pig iron [1] in the United States in 1972, by type of consumer and type of furnace or equipment

(Thousand short tons)

Type of furnace or equipment	Manufacturers of steel ingots and castings [2]		Manufacturers of steel castings [3]		Iron foundries and miscellaneous users		Total all types	
	Scrap	Pig iron	Scrap	Pig iron	Scrap	Pig iron	Scrap	Pig iron
Blast furnace [4]	3,565	--	--	--	--	--	3,565	--
Basic oxygen converter [5]	24,192	60,233	--	--	--	--	24,192	60,233
Open-hearth furnace	18,638	22,361	187	14	--	--	18,825	22,375
Electric furnace	24,886	777	2,165	34	3,408	150	30,459	961
Cupola furnace	1,759	330	278	5	13,507	1,929	15,544	2,264
Air furnace	32	84	33	7	121	48	186	139
Other furnaces [6]	343	247	1	--	256	7	600	254
U.S. total	73,415	84,032	2,664	60	17,292	2,134	93,371	[7] 86,226

[1] Excludes molten pig iron used for ingot molds and direct castings.
[2] Includes only those manufacturers of steel castings that also produce ingots.
[3] Excludes companies that produce both steel ingots and steel castings.
[4] Includes consumption in all blast furnaces producing pig iron.
[5] Includes scrap and pig iron processed in metallurgial blast cupolas and used in oxygen converters.
[6] Includes vacuum melting furnaces and miscellaneous melting processes.
[7] Excludes pig iron used in making molds and poured directly into castings.

Table 4.—Proportion of iron and steel scrap and pig iron used in furnaces in the United States

(Percent)

Type of furnace	1972	
	Scrap	Pig iron
Basic oxygen converter	28.7	71.3
Open-hearth furnace	45.7	54.3
Electric furnace	96.9	3.1
Cupola furnace	87.3	12.7
Air furnace	57.2	42.8

Table 5.—Iron and steel scrap supply[1] available for consumption in 1972, by State and region

(Thousand short tons)

State and region	Receipts	Production	Total new supply	Shipments[2]	New supply available for consumption
New England: Connecticut, Maine, New Hampshire, Massachusetts, Rhode Island, and Vermont	228	145	373	12	361
Total	228	145	373	12	361
Middle Atlantic:					
New Jersey	505	137	642	8	634
New York	1,129	1,556	2,685	220	2,465
Pennsylvania	7,585	11,462	19,047	1,812	17,235
Total	9,219	13,155	22,374	2,040	20,334
East North Central:					
Illinois	5,598	4,203	9,801	414	9,387
Indiana	2,855	8,754	11,609	660	10,949
Michigan	5,658	4,347	10,005	189	9,816
Ohio	7,930	9,058	16,988	1,424	15,564
Wisconsin	527	398	925	21	904
Total	22,568	26,760	49,328	2,708	46,620
West North Central: Iowa, Minnesota, Missouri, Nebraska, and Kansas	1,918	634	2,552	116	2,436
Total	1,918	634	2,552	116	2,436
South Atlantic:					
Delaware, Maryland, and West Virginia	1,566	3,139	4,705	81	4,624
Florida and Georgia	682	136	818	2	816
North Carolina, South Carolina, and Virginia	1,193	279	1,472	12	1,460
Total	3,441	3,554	6,995	95	6,900
East South Central:					
Alabama	1,753	2,009	3,762	69	3,693
Kentucky and Mississippi	928	930	1,858	163	1,695
Tennessee	780	265	1,045	12	1,033
Total	3,461	3,204	6,665	244	6,421
West South Central: Arkansas, Louisiana, Oklahoma, and Texas	2,723	1,368	4,091	88	4,003
Total	2,723	1,368	4,091	88	4,003
Mountain and Pacific: Arizona, Colorado, Montana, Nevada, Utah, California, Washington, and Oregon	3,562	2,364	5,926	147	5,779
Total	3,562	2,364	5,926	147	5,779
U.S. total	47,120	51,184	98,304	5,450	92,854

[1] New supply available for consumption is a net figure computed by adding production to receipts and deducting scrap shipped during the year. The plus or minus difference in stock levels at the beginning and end of year is not taken into consideration.

[2] Includes scrap shipped, transferred, or otherwise disposed of during the year.

Table 6.—Consumption of iron and steel scrap and pig iron [1] by State and region, by type of manufacturers in 1972
